Continental Portugal, excluding the Azores and Madeira, was 5,621,997 in 1920, and its area 34,254 square miles. Registration, the complement to the census for statistical purposes, formerly in Portugal entrusted to the clergy, has since 1900 been in the hands of civil authorities. In 1911 it was made compulsory, and failure to register is now a penal offence. Every live birth must be declared within one month at the local registrar's office by the father, or other specified person in his default. A similar rule obtains for stillbirths, the period of gestation being recorded in both cases. Every death must be declared immediately, in presence of two witnesses to the fact of death, by the nearest relative, or other specified person in his default. The medical practitioner who attended the deceased in his last illness must hand to the family a certificate of the fact of death and its primary and contributory causes. Registration summaries are sent monthly to the central statistical department from all local areas. The birth rate of Portugal, from 1913 to 1920 inclusive, ranged between 26.4 and 33 per thousand. The death rate, from 1911 to 1920 inclusive, ranged from 19.4 to 40.2, the latter high figure belonging to 1918, the influenza year. In 1920 it was 25.5. Two causes of death show a disparity with English returns. For cancer the frequency ratio of Portugal to England is as 1 to 4, for ill defined causes as 10 to 1. This low cancer rate, combined with a high rate for ill defined causes, is probably a matter of diagnosis. The birth rates and general death rates quoted may reflect the facts, they may, on the other hand, be misleading—if, for example, the annual population on which they are based, calculated presumably from the census of 1911, were underestimated. As regards the census for 1911 no opinion can be expressed. As to the census of 1920 the comments of the Director-General may be left to speak for themselves. Had control been rigidly centralized it is likely that the irregularities to which he refers would have been substantially reduced. Be that as it may, an essential requirement for the compilation of vital statistics in Portugal or any other country is a sound population figure.

#### BIRTHS AND DEATHS REGISTRATION ACT, 1926

Mr GEORGE P. STRATHFARN, honorary secretary of the Association of Registrars of Scotland, informs us that a number of medical practitioners in that country are sending death certificates direct to registrars under the impression that they are required to do so by the new Registration Act. It should be noted that this impression is erroneous. The Births and Deaths Registration Act, 1926, the new Act in question, does not apply to Scotland or Northern Ireland. Any change of procedure which it involves affects England and Wales only.

#### THE ANNUAL MEETING TWO CORRECTIONS

In our reports last week of the Annual Meeting of the British Medical Association at Edinburgh, there were two mistakes which need only correction. The number of those attending the Annual Dinner was in fact more than twice the figure mentioned. No fewer than 678 members of the Association and guests were present. Again, the winner of the Ulster Golf Cup this year is Dr A. J. Cronin, not Dr J. A. Cronin, as stated at p. 79 of the Supplement.

By an Order of the Committee of Privy Council, Sir Hugh K. Anderson, M.D., F.R.S., Master of Gonville and Caius College, Cambridge, and Professor T. R. Elliott, M.D., F.R.S., Director of the Medical Unit, University College Hospital, London, have been appointed members of the Medical Research Council into the vacancies created by the retirement of Sir Frederick Andrewes and Sir Cuthbert Wallace.

## THE HISTORICAL MEDICAL EXHIBITION AT THE EDINBURGH ANNUAL MEETING

In connexion with the History of Medicine Section at the Edinburgh Meeting of the British Medical Association, an interesting historical medical exhibition was shown in the Upper Library Hall of the University. A large portion of the exhibits were lent by the Wellcome Historical Medical Museum, by the courtesy of Mr. Henry S. Wellcome, who was one of the vice presidents of the Section.

Surgery became a science in recent times, not so much through individual skill as through the introduction of two new factors—anaesthesia and antiseptics. The earliest surgical instrument was in all probability some fragment of flint or of fish's tooth, with which blood was let, abscesses emptied, tissues scarified, skulls trephined, and, at a later date, operations like circumcision performed. Trephining for epilepsy goes back to primitive times, the bits of skull excised being used for amulets. Primitive man's wounds were dressed with moss or fresh leaves, ashes, or natural balsams, and, when poisoned, were

treated by sucking or cauterization. Cupping was performed by means of animals' horns. For couching a cataract or opening an abscess even a sharp thorn sufficed, but in more advanced stages of development pieces of hardened wood may have been pointed and edged like the flint knives. Examples were shown of knives belonging to medicine-men from the Congo, as well as various Sudanese surgical instruments, and glass surgical knives from Mexico, Australia, and other places. There were also horns and gourds to illustrate the evolution of the cupping vessel, along with specimens of Roman and Arab cupping vessels, and specimens of shells,

stone knives, etc., showing the development of the lancet from the sharpened finger nail through the stage of the thorn and bamboo, to the modern instrument.

Specimens of surgical instruments of the sixteenth, seventeenth, eighteenth, and nineteenth centuries were also shown. These were mainly knives and saws for amputation, and instruments for extracting bullets from wounds, and there was also a curious instrument, first described by Guv de Chauliac in 1300, for widening a wound in order to extract an arrow-head.

The chief method of Greek healing was by recourse to the Temples of Aesculapius, where advice was received by the patient in a dream interpreted to him later by the priests. If the treatment was successful the patient then presented a thank-offering to the god, usually a model of the diseased part in wax, silver, or gold while a votive tablet, giving the history of his case and its treatment, was suspended in the temple. These tablets formed the permanent clinical records of the Coan and Cnidian schools of medicine, in the first of which Hippocrates was himself a pupil. Several interesting examples of these votive offerings were exhibited, including plaques showing internal viscera, a fragment of a trunk showing digestive organs, and several small figures of diseased patients.

The highest point of development in ancient surgical treatment was reached in India. In the Susruta (fifth century A.D.), one of the three leading texts of Brahminical

medicine, about 121 different surgical instruments are described. These include scalpels, lancets, saws, scalps, needles, hooks, probes, directors, sounders, forceps, trocars, catheters, syringes, bougies, and a rectal speculum. The Hindus apparently knew every operative procedure except the use of the ligature. All these instruments were properly handled and pointed, the blades sharp enough to cut a hair, and kept clean by wrapping in flannel in a box. Examples of all the instruments mentioned above were shown.

Under the Romans surgery attained a degree of perfection which it did not again reach till the time of Ambrose Pare. Surgical instrumentation, in particular, was highly specialized, and in the ruins of Pompeii over two hundred different surgical instruments were found. Herniotomy and plastic surgery were known, as well as the operations for cataract, version, and Caesarean section. In this section of the museum were shown specimens of specula, catheters, elevators, trocars, canteries, and forceps belonging to the first century A.D., with a twentieth century example of the same instrument alongside. It was

interesting to note the striking similarity between each pair of specimens, maintained over this period of two thousand years, many of the modern instruments being practically identical with their ancient prototypes.

Surgery in Scotland was revolutionized in the sixteenth century by Peter Lowe who had been a surgeon in the French Army, and in 1599 came to Glasgow, where he founded the Faculty of Physicians and Surgeons. A set of dental instruments of types described by Peter Lowe was shown as well as French pocket instrument cases of the eighteenth and nineteenth centuries, and there were numerous specimens of scarifi-

THE HISTORICAL MEDICAL EXHIBITION IN THE LIBRARY HALL, EDINBURGH UNIVERSITY.

[The Secretary

cators. All these exhibits were from the Wellcome Historical Medical Museum, London. The medicine chest of Prince Charles Stuart, lent by the Royal College of Physicians of Edinburgh, was also shown.

An excellent idea of the conditions of early and mediæval medical and surgical treatment was to be gained from the many black and white and coloured illustrations displayed in the alcoves of the hall. They were divided roughly into illustrations of physicians and patients, depicting clinical methods, etc., of the thirteenth to seventeenth centuries, cauterization, which was shown as being used for epilepsy, falling sickness, sciatica, difficulty in breathing, and for diseases of the lungs, kidneys, liver, spleen, bladder, etc., bleeding which was employed with great freedom as a remedy from early times, surgical procedures, illustrating operations for stone fractures, tooth-drawing, reduction of dislocations, circumcision, and military operations, mainly amputations, and anatomical illustrations, which consisted chiefly of diagrams of the human body showing the veins for blood-letting and pictures of anatomical instruments. These also were lent by the Wellcome Museum.

An interesting collection of obstetrical instruments from the Obstetrical Museum of the University of Edinburgh was on view, and at the other side of the hall there was a collection of engravings from the Royal College of Physicians of London. These included portraits of Lamer-

and Carius, and passed on to Sydenham, Harvey, Wilks, and other celebrated physicians of the seventeenth century. Many of the physicians of the later Stuart and Queen Anne periods, such as Sir Richard Blackmore, Sir Samuel Garth, Sir Hans Sloane, Dr Richard Mead, and Dr John Radcliffe, were also represented. Good engravings of Sir James McGilgor, John Hunter, Edward Jenner, Sir Charles Hastings (the founder of the British Medical Association), and other men eminent in the nineteenth century, completed the series. The collection was one which well repaid inspection, both on account of its medical associations and its artistic merit.

A collection of pictures of former teachers in the Edinburgh medical school was another noteworthy feature of the exhibition. These included physicians such as John Rutherford, the first lecturer on clinical medicine in the Royal Infirmary, the celebrated William Cullen, Archibald Pitcairne, John and James Gregory, Professors Hughes Bennett, Alison, Sir Thomas Granger Stewart, etc. Among the surgeons there were fine portraits of Robert Liston, Sir William Ferguson, James Syme, and James Miller, and there were also groups showing professors and teachers in the Edinburgh school at different epochs.

A series of portraits of eminent past students of Edinburgh included three generations of Darwins—Easmus Darwin, Robert Waring Darwin, and Charles Darwin—and a number of engravings of portraits by the celebrated Scottish painter Raeburn, including Professors Thomas Charles Hope, Joseph Black, Alexander Monro, and others. There was also an interesting collection of pictures of celebrated American physicians and surgeons who graduated at Edinburgh.

A series of water-colour sketches by Sir Daniel Wilson, showing various old Edinburgh buildings, and particularly several views of parts of Trinity Church and Hospital, was on view. These are the property of the University of Edinburgh. In the cases there were numerous illuminated manuscripts and old printed books, many of them medical, the property of the University. There was also an interesting collection of relics of Dr John Fothergill, including diplomas, letters, books, and personal possessions, together with many other objects of medical and historical interest.

The exhibition was visited by over 5,000 members of the British Medical Association and of the public during the four days that it remained open.

## RESULTS OF TREATMENT OF UTERINE CANCER

ONE of the more important reports on medical subjects published by the Ministry of Health is that issued last month under the title of "Cancer of the uterus: a statistical inquiry into the results of treatment, being an analysis of the existing literature." The report is written by Dr Janet E. Lane-Claydon and is based on an examination of data contained in medical publications at home and abroad prior to March, 1926. The articles examined are derived from sixteen different countries, are 848 in number, and relate to the records of some 80,000 cases of the disease. The mere collection and sifting of the data from this mass of material must have been a work of great magnitude, and the results, embodied in twenty-four variously classified appendices, will form a permanent work of reference the value of which cannot fail to be appreciated by those interested in the subject. In addition, the author has applied statistical methods in extracting several deductions of great interest. The most important of these relates to the relative values of abdominal hysterectomy and radiation in the treatment of carcinoma of the cervix uteri, the figures pointing to the conclusion that for the cure of the disease, that is to say, to obtain a survival rate of five years and over, treatment by radium is almost as efficient as abdominal hysterectomy. This conclusion is based on cases reported from Germany, Austria, America, Sweden, France, Switzerland, and Belgium, England being conspicuous by its absence from the list. Referring to this point, Sir George Newman, in his prefatory note, remarks "One is im-

pelled to inquire whether these remedial agents, radium and roentgen rays, are used as widely as they should be and with similar results in England." It is difficult to believe that so distinguished a school of gynaecology as the English can be lagging behind the Continent in the matter of radium treatment, and Sir George Newman suggests that the absence of records may be due to a disinclination of gynaecologists and radiologists to publish accounts of series of cases, to an absence or incompleteness of clinical records, and to a lack of any system of ascertaining after-histories. If the results in this country are at all comparable with those obtained on the Continent it is to be regretted that they are not put on record, on the other hand, if the claims made for radium treatment are untenable it is still more important that the fact should be made known.

In discussing the various methods of treatment in cases of carcinoma of the cervix, Dr Lane-Claydon states that it is only necessary at the present day to consider the relative merits of two—namely, abdominal hysterectomy and radiation—and the first part of her report is concerned with a comparison of these two methods. In order to simplify the inquiry, no consideration is given, in the first instance, to the stage of the disease at the time of operation, the cases are merely classified into operable and inoperable, differences indicated by such terms as "borderland," "early," and "advanced" being excluded. In order to compare the two methods on this basis it is necessary to take out four sets of data: (1) the total number of applicants, (2) the operability, that is the number of patients reckoned operable out of the total number of applicants, (3) the immediate operative mortality, and (4) the number of survivors at five years after treatment, having regard to the total number of applicants as well as to the total number treated. With regard to the ratio of operability, several circumstances combine to render this a fluctuating figure. Thus there was an almost universal increase in the number of inoperable patients during the period of the war, which has not yet everywhere disappeared. Again, the personal opinion of the individual surgeon as to what cases should be considered operable must be a very considerable factor. Also a great increase in inoperable cases was noted in many clinics after the introduction of radium treatment in 1913, women being apparently more willing to come forward in view of the alternative to surgical treatment, and surgeons probably now regarding some advanced cases as inoperable which, in the absence of radium, would have been recommended for operation. As to the method of obtaining the operability figure, it was found impossible to discriminate between the standard of operability adopted by different surgeons; then figures have been accepted and a mean operability calculated on the basis of the massed figures. Even so it was found that the mean operability could not be calculated for all authors, since many fail to state the number of inoperable cases in their practice, and, where the figures are given it is by no means certain that they afford the total number of women making application. The mean operability thus calculated was found to be, in the case of abdominal hysterectomy, 48.9 per cent, and in the case of radiation, 40.8 per cent, the lower percentage in the case of radiation being due probably to the increase already mentioned of inoperable applicants following the introduction of radium. With regard to the operative mortality, no difficulty was found in estimating the percentage, large samples were available, the percentage for abdominal hysterectomy was 17.3, that for radium nil. Although deaths have undoubtedly occurred after radiation they have been few and have occurred chiefly at a time when the dangers of radiation were not appreciated. With regard to the survival rates, it is important that these should be calculated on the total number of applicants, both operable and inoperable, since a surgeon might readily produce a high percentage of survivors by the simple process of declining to operate on the more advanced cases. It would have seemed necessary also to have taken into account those patients whose fate could not be ascertained, and those known to have died within the five-year period from some cause other than cancer. It appears that these cases can safely be left out of consideration, since it has been recently shown in this country that the

united cases form a reasonably fair sample of the whole. Finally, with regard to the total number of applicants, it was mentioned above that some authors fail to record the totals in their practice, where this is the case the assumption has to be made that the total number bears a definite relation to the number of cases operated on, taking the standard mean operability rate into consideration. The results of this part of the investigation are set out in the following table:

	Abdominal by the operator	Radiation.
Operability	48.9	40.8
Operative mortality	17.3	—
Survival rates		
Total cases	18.3	22.0
Inoperable cases excluded	37.6	35.8

Thus if the inoperable cases are included radiology gives the better results but if they are excluded then operative surgery shows a slight preponderance of survivors. Radiation has the further advantage that in inoperable cases it can show a survival rate of 12.7 per cent.

In view of the very wide divergences in the survival rates shown by individual surgeons, Dr. L. C. Clayton has endeavoured to obtain more definite indications of the relative value of the two methods by taking out figures of authors who had published results of not less than one hundred consecutive cases treated exclusively by one or other method. In these selected series there still appeared such wide divergences that no general deductions have been found possible. The remainder of the report deals with the results of treatment in relation to the stage of the disease at the time of treatment, with questions as to the influence of age and civil state, of the symptoms and their alleged duration, of the infection of the glands, and of the dissemination of the disease in the body, a final section is devoted to cancer of the body of the uterus.

## MATERNAL MORTALITY AND MORBIDITY IN VICTORIA

Australia, like the mother country and the other Dominions, has been exercised about her puerperal mortality, and in the State of Victoria the report of a committee appointed by the Victorian Branch of the British Medical Association in 1924 to consider the matter had important consequences. Among them was a gift of £10,000 to the University of Melbourne for the appointment of a director of obstetrical research, whose duty was to inquire into the causes of maternal mortality and disability in Victoria and to suggest means to prevent or lessen both.

An interim report by the director, Dr. R. Marshall Allan,<sup>1</sup> presents many points of interest, particularly in that he has made a survey of domestic obstetric practice as well as of the work of hospitals and other institutions public and private. All practitioners in the State were interviewed and personal interviews obtained with 239 of them, both in Melbourne and throughout the country districts. The part of the report dealing with the director's observations on midwifery in private practice appears to be as applicable here as in the Antipode, and is certainly worthy of detailed study.

The author takes a decidedly optimistic view of the improvement in midwifery practice in Victoria and is not inclined to accept the statement in Dame Janet Campbell's report on maternal mortality,<sup>2</sup> that while the general death rate has been reduced by a third and the infant mortality halved, since the beginning of the century, the maternal mortality has been little affected. He gives figures for his own State to show that there has been a decrease of 22 per cent in the general death rate and 31.5 per cent in infantile mortality as compared with one of 23 per cent for all puerperal causes. Of the latter, sepsis decreased by 38 per cent and the rate for other causes by 17 per cent. It is to be noted, however, that

the statistics on which these findings are based are not of five-year periods, but of two selected years, 1905 and 1925. In contrast to Dame Janet Campbell's report the investigation into the results obtained in domestic practice allows of the inclusion of the records of successful work, although the manner in which they are stated leaves their precise meaning uncertain.

In one case quite an elected or sixteen men who had delivered between one thousand and two thousand women the average mortality was two. Another group of fifteen doctors who had delivered more than two thousand women had only one at an average of three patients.

In regard to ante-natal supervision attention is drawn to the handicap caused by the custom of many expectant mothers to engage their nurse early in pregnancy and not to visit the doctor till near the end or until labour begins. Dr. Allan states also that there is little trouble in keeping in touch with women in their first pregnancy, whereas the multiparous tend to be irregular in attendance. His conclusion is that save in some of the industrial areas, ante-natal supervision is good and that the public is being rapidly educated to its value.

Of the confinements 60 per cent take place in hospitals public or private the proportion varying with the locality and the reputation of its hospital. The report is emphatic on the need for the establishment of large modern maternity units with accommodation at reasonable rates, as by their establishment much of the drudgery of obstetrics and the temptation to force the natural sequence of events would be avoided.

Regarding the vexed question of forceps delivery the actual words of the report may be quoted:

The number of patients requiring the application of forceps varies from 10 per cent to 80 per cent with individual men. Those who employ them as a routine are invariably busy practitioners and confess that it is due to pressure of work. Poutine's application is denuded on two grounds: (1) The saving of the perineum; (2) the absence of any had after-effects. On the other hand many men are not so optimistic about the prevention of lacerations with the forceps. While no records have been given in support of these views the figures of St. George's Hospital, New in a district where the collective skill of the practitioners is certainly not below the average are instructive. Forceps were applied in the case of 19 per cent of the women and the percentage requiring suture was as great as with the following natural delivery. The total morbidity of all patients was 7 per cent while that of those who had forceps delivery was 10.5 per cent.

The remarks on operations for contracted pelvis and Cæsarean section are interesting. The report acknowledges that the family practitioner is not usually able to give any details as to the degree of pelvic contraction, and then goes on to say: "It is difficult to understand why some men have a monopoly of cases, whilst colleagues equally busy in the same suburb hardly ever see one."

Surely there is no difficulty in understanding this apparent anomaly. In protracted labours several factors are very often present—a trifling degree of contraction, relative weakness of the forces, a large or unduly hard head with perhaps some degree of extension or a persistent posterior position. No two obstetrists may agree as to the prominent factor, but to many the simple mechanical explanation of pelvic contraction is the easiest and simplest and is accepted as the cause of delay. Thus in a country where rich and contracted pelvis are rarities, a monopoly in contracted pelvis may be readily acquired by the simple process of ascribing all difficult and delayed labour to pelvic deformity. The remarks on treatment are also worth quoting:

Too few are given a trial of labour and it would be desirable if operation were deferred until reputable consultants had occurred as to its necessity. I have collected the records of one hundred and thirty-two Cæsarean sections with a maternal mortality of 10 per cent for all indications. Too many are performed for contracted pelvis, placenta prævia, and other conditions. The mortality following this method of treating cases of placenta prævia does not compare favourably with that following more conservative methods.

The director concludes that the public needs much more education regarding the danger and uselessness of injudicious interference in labour, also that the profession is not combining to raise the dignity of the obstetrical art especially by limiting the amount of midwifery which can be undertaken in a given period.

The amount of puerperal sepsis in private practice was

<sup>1</sup> Interim Report on Maternal Mortality and Morbidity in Victoria by R. Marshall Allan, M.D., F.R.C.S.E., Director of Obstetrical Research, University of Melbourne. Reprinted from the *Medical Journal of Australia* January 14, 1927.  
<sup>2</sup> *Ministry of Health Reports*, No. 22.

found difficult to estimate owing to lack of records, but, in the majority of cases, is stated to have followed some operative intervention. The cause was blamed only in a small proportion of cases, but the general opinion among the practitioners was that most of the infections occurred in the smaller type of hospital and not in private houses.

In summarizing the results of his inquiries, Dr Allan expresses the view that the high ideals set before students by their teachers are beginning to show results, and that he is able to see this improvement more clearly than others because he has been in a position to view it apart from the daily worries of practice. On the other hand, he utters a warning to the effect that the first result of an awakened professional conscience will be a rise in the statistical rate due to a more accurate certification of the cause of death, at present there is a disposition to take shelter behind a fictionally low mortality rate.

Clinical and laboratory investigations are being conducted at various maternity institutions, and accounts of them will be presented in the final report next year.

## Nova et Vetera.

### HANGED, DRAWN, AND QUARTERED

THERE is a good deal of grim interest in the forms of punishment that are now obsolete in this country. The pillory, the ducking-stool, the brank or scold's bridle, the whipping-post, and stocks are well known forms of punishment that are no longer in use. Among the rarer forms may be mentioned the *peine fort et dure*, or pressing to death, burning to death, and boiling to death. This latter was not allowed by the common law, but in order to deal more effectually with the crime of wilful poisoning a new statute was passed in the twenty-second year of Henry VIII, which made high treason punishable by this grievous and lingering death, without benefit of clergy.

The full punishment in the execution of traitors, although not absolutely done away with until the year 1870, cannot frequently have been inflicted for the last hundred years. From the thirteenth to the fifteenth century this sentence was often carried out at many of the principal cities and towns of the kingdom. In every case of high treason, save in the crime of coining, the sentence was that the offender be led to the gall from whence he came, and from thence be drawn to the gallows and there hanged by the neck, that being alive, he be then cut down and his entrails taken out and burned, that his head be cut off and his body divided into four quarters, the head and quarters to be at the disposal of the Crown.

In the *Chronique de la Traison et Mort de Richard Deux Roy d'Angleterre*, translated by Benjamin Williams, F.S.A. (English Historical Society, 1846), is given the following account of this ghastly business in the case of certain of King Richard's adherents:

"The king (Henry the fourth) commanded his chamberlain Sir Thomas Erpingham to have justice executed upon the lords who were taken prisoners, and to put them all to death except a young knight whom he had dubbed the Saturday before his coronation, whom the king pardoned for rising in arms against him, on account of his youth and noble lineage. Sir Thomas Blount and Sir Benet (Shelley) were drawn from Oxford unto the place of execution a long league or more, and there they were hung, they then cut them down and made them speak, and placed them before a huge fire. Then came the executioner with a razor in his hand, and kneeling down before Sir Thomas Blount, who had his hands tied, begged his forgiveness for putting him to death, for he was obliged to perform his office. 'Aie you he' said Sir Thomas, 'who will deliver me from this world?' The executioner replied, 'Yes my lord I beg you to pardon me. The king by pardon is all forgive him. The executioner had hysterectomy. This conelazoi and kneeling between the fire from Germany, Austria, AntThomas Blount and ripped open land, and Belgium, England with a piece of whipcord that absence from the list. Refereis escape, and erst the bowels Nowman, in his prefatory note, as Erpingham said, Now

bo the hour when I was born, and blessed be this day, for I die this day in the service of my sovereign lord King Richard. After he had thus spoken, Sir Thomas Erpingham asked him, 'Who are the lords knights and esquires who are of your accord, and treason?' To which the good knight replied, suffering as he was, 'Art thou the traitor Erpingham?' Thou art more false than I am or ever was, and thou heest, false knight as thou art, for, by the death which I must suffer, I never spoke ill of any knight, lord or esquire, nor of anybody in the world, but thou utterest thy false spleen like a false and disloyal traitor, for by thee, and by the false traitor the Earl of Rutland, the noble knightlyhood of England is destroyed. Cursed be the hour when thou and he were born! I pray to God to pardon my sins and thou traitor Rutland, and thou false Erpingham, I call you both to answer before the face of Jesus Christ for the great treason that you two have committed against our sovereign lord noble King Richard, and against his noble knightlyhood. The executioner then asked him if he would drink. 'No' he replied, 'you have taken away wherein to put it, thank God!' and then he begged the executioner to deliver him from this world, for it did him harm to see the traitors. The executioner kneeled down, and, Sir Thomas having kissed him, the executioner cut off his head and quartered him, and he did the same to the other lords, and parboiled the quarters. And in Oxford castle many other knights and esquires were beheaded.

Without wishing to be facetious over this grim affair, one may wonder at the refinement of cruelty of asking a man to have a drink in such circumstances, and at the fortitude of Sir Thomas Blount, as shown in his answer.

From a medical point of view the chief interest in these cases is the fact that a man on whom this barbarous sentence had been inflicted was yet able to retain consciousness and to answer questions. I assume that the executioner cannot have made a very large incision with his razor. If he had ripped up the abdominal wall and removed the mass of the intestines, the shock, I should think, must have been such as to make the patient unconscious at once. I assume that he can have made only a small incision, through which a knuckle or two of gut may have protruded, with a piece of the great omentum, this prolapse must have been tied and cut off, if he had divided the abdominal cavity of only the gut the shock would have been so great as to lead to instant death, at least that is how it strikes me, perhaps some surgeon can enlighten me.

In Sir Thomas Blount's speech to the chamberlain, it might be thought that what he intended to say was "thou art the traitor, Erpingham." The query is inserted here because it is in the text, and on looking up the original French on page 91 I find "*Es tu le traitre Erpinghem tu es plus faulx,*" etc.

R. R. JAMES

## New Zealand.

[FROM OUR CORRESPONDENT]

### DURATION OF LIFE

At the meeting of the American Public Health Association Professor Irving Fisher of Yale University expressed the opinion that increases in length of life are being attained at an amazing rate. He believes that the average length of life in 1930 will be 61, in 1940 65, in 1950, 69, in 1960, 72. Whereas in America the expectation of life is at present 58 years, in New Zealand female lives have already reached an expectation of 65 years. The male expectation of life in New Zealand is 62½ years and these islands appear to enjoy the longest expectation of life of any country in the world.

### SCHOOL DENTAL CLINICS

Since 1921 school dental nurses have undergone a limited but intensive training for work in dental clinics to cope with widespread dental crises in the children attending the State primary schools in New Zealand. The scheme has been approved by the New Zealand Dental Association, the members of which are frankly unable to touch more than the fringe of this work, which is felt to be of high national importance from the public health point of view. Experienced dentists now speak of very obvious improvement in the condition of the teeth of school children. In the year 1926 the dental nurses undertook 50,375 fillings,

53,387 extractions, and performed 43,452 minor operations. At the present time fifty-eight clinics are established, and 53,000 children are receiving regular dental attention. It is not only in actual treatment that good work is accomplished. The pamphlets distributed to each child on diet and oral prophylaxis are commendable, and have an educative effect upon the parents. Many parents are inclined to be careless, and others cannot afford the expense of having their children's teeth regularly attended to. A nice point is the extent of skilled work that should be executed by dental nurses with their relatively limited training, but that a proper limit is set is in evidence in the fact that the president of the New Zealand Dental Association advocates the extension of the scheme to all State primary schools. This extension would necessitate increasing the staff, and presumably also the expense, sixfold. The aim at present is to treat all the children who require treatment to the age of 9 years, and as far as possible to follow up this treatment to the end of the child's school career. The department cannot with its present staff instruct more than forty dental nurse pupils, and the period of training extends over two years. Claims have been made on behalf of private schools for the services of the school dental nurses, but the Minister of Health considers that the children in the State schools have first claim, and cannot at present see his way clear to incur the further expenditure necessary to overtake the dental work required for the full total of 200,000 children attending the State primary schools in New Zealand.

During the war period it was found that the extent of dental decay in recruits was amazingly great, and this was an important factor in the attempt to lessen the evil by beginning with young children in the schools. There is evidence that the education of parents in the need for regular dental attention to children is extending, but progress in this direction is slow. Probably benefits which are easily and cheaply attained, or which cost nothing, in public health matters as well as in education, are not sufficiently highly valued, but whatever may be said by way of adverse criticism there is no doubt that investigation revealed in New Zealand a deplorable bad state of dental sepsis in children which the dental profession was unable to treat adequately, and the system of dental clinics staffed by school dental nurses has been a pronounced success.

## England and Wales.

### X-RAY SERVICE IN LONDON MENTAL HOSPITALS

FOLLOWING a suggestion made by the Board of Control that valuable aid to diagnosis would be forthcoming if x-ray apparatus were available for each of the London mental hospitals, the mental hospitals committee of the London County Council is considering as to the best method of securing an efficient x-ray service. In the meantime, tentative arrangements have been made for obtaining radiographs as required, and as an experiment it is proposed to engage a consultant radiologist for one year to read and advise on radiographs in difficult cases. The fee suggested is one guinea (inclusive) for each case reported upon by him.

### Tuberculosis After-Histories

A report was furnished to the London County Council at its last meeting on the after-histories of persons who approximately five years ago, were discharged after residential treatment under the council's tuberculosis scheme. The patients, as in previous reports of the same kind are divided into several categories. A, cases in which tubercle bacilli were not found in the sputum, B, cases in which the sputum contained tubercle bacilli, these were divided into three groups, according to the severity of the disease—namely, B1, cases with slight constitutional disturbance, if any and obvious signs of very limited extent. B3, cases with profound disturbance or constitutional deterioration, and B4 cases with grave complications, and B2, cases not falling into groups 1 and 3. Thus cases described as A and B1 may be regarded as early, B2 as moderately

advanced, and B3 as far advanced. During 1921 the number of adults discharged after treatment was 4,094, of whom 2,746 were civilians and 1,348 ex-service men. In 348 cases the diagnosis of tuberculosis was not confirmed, of the remainder (3,746) 350 were not traceable and 218 were discharged from observation hospitals within a few weeks of treatment and were not transferred to sanatoriums. The number of cases investigated, therefore, five years after discharge was 3,178, including 223 surgical cases. The records showed the following results five years afterwards:

Class	Total	All-free 5 years after discharge	Dead
A	463	83.5%	16.5%
B1	350	61.5%	38.5%
B2	1,299	34.0%	66.0%
B3	838	3.7%	96.3%
Surgical	223	75.5%	24.5%

Particulars obtained as to the fitness for work of the 1,230 surviving patients who were discharged from treatment in 1921 show that out of a total of 594 A and B1 cases, 63 per cent were at work, which was considered satisfactory testimony to the value of sanatorium treatment when applied to cases in the early stage of the disease. The proportions at work in the other categories were B2, 40 per cent, B3, 25 per cent, and surgical, 71 per cent. Of the total number of 1,230 in all categories 57.5 per cent were at work, 4.4 per cent were fit for work but were unemployed, and 37.5 per cent were unable to work (including cases receiving further treatment) the condition of the remaining 0.6 per cent was not known.

### Proposed Segregation of Mental Defectives

The London County Council at its meeting on July 26th had before it a resolution from the Leicestershire County Council to the effect that the segregation of mentally defective persons unless accompanied by active measures for the prevention of the propagation of the mentally unfit, was likely to impose an unfair and continually increasing financial burden upon the public, and that legislation should be promoted in order to make illegal the marriage of any certified mentally defective person and to legalize a system of voluntary sterilization, with subsequent supervision of mentally defective persons. A similar resolution was also received from the Southampton County Council. The London County Council was not prepared to agree that surgical sterilization should be adopted as a prophylactic for mental deficiency but passed a resolution that legislation should be promoted by the Government to make illegal the marriage of a person who was for the time being subject to an order of detention under the Mental Deficiency Act. On the other parts of the resolutions from Leicestershire and Southampton it was decided to take no action.

### HEALTH OF LONDON IN 1926

Volume III of the annual report of the London County Council for 1926 consists of the report of Dr. Menzies as county medical officer, and his report as school medical officer together with chapters on public health, main drainage, and housing.

### General Statistics

The total population of the County of London in the middle of 1926, according to the Registrar-Generals estimate, was 4,615,400 including 10,000 non-civilians, being an increase of 91,400 since last census five years ago. As the excess of births over deaths during the period was 165,500 there has been a loss by excess of emigration over immigration of about 74,000 persons. The marriage rate for 1926 was 17.2 per 1,000 the same as in the previous year. The birth rate was 17.1 as against 17.9 in 1925, and 18.6 in 1924. It is suggested that the decline in the general birth rate of the country began with the Factory and Education Acts, which lowered the value of children as wage earners, and continued owing to the fall in the marriage rate due to the delayed wage earning power of the youths compulsorily educated. Since 1910 despite the revival of the marriage rate among women minors the fall in the birth rate has been accelerating. The deaths in

London in 1926 were 53,476, being 1,485 more than in 1925, which had the lowest record. The excess is due to circulatory disease and cancer at higher ages, measles in children under 5, and vehicular traffic.

### *Infectious Diseases*

Five cases of small-pox occurred during the year. Two separate channels of invasion were traced, both originating from Paris. There was one death, that of a woman who had not been vaccinated since infancy. The notified cases of diphtheria numbered 13,526 and the deaths 547. Of 302 notifications of typhoid fever with 31 deaths, 5 were ascribed to fried fish. Of 7 cases of anthrax 5 were infected by foreign hides and 1 by feathers from China. One case died, an infant in Paddington, the source of infection remaining obscure. There were 83 cases of poliomyelitis, 8 of these, and 2 unnotified cases died. Of 173 cases of encephalitis lethargica 68, together with 22 unnotified cases, died. Between 1919 and 1925 there were 1,325 cases, of whom 495 died. An analysis of the survivors reveals that 373 are now apparently well, 61 have slight sequelae, 100 have incommoding sequelae, 180 are wholly incapacitated, and 116 are untraced. Though the 100 chronic encephalitis beds at Winchmore Hill fall short of native requirements extra-metropolitan authorities are asking for the treatment of persons resident outside London.

### *Tuberculosis*

Deaths from tuberculosis during the year were 4,066, giving an annual death rate of 0.88 per 1,000, and for other forms 691, corresponding to a death rate of 0.15 per 1,000. The view is expressed that in comparing the incidence of phthisis in different populations more attention should be paid to the death rate in each from all causes. Three groups of metropolitan boroughs representing three different social grades are shown to differ widely in their phthisis death rate, yet the relative incidence of phthisis, expressed as a percentage of deaths from all causes, is much like in all. This contention is discussed also in its relation to Dr. Brownlee's three types of phthisis.

### *Cancer*

The deaths from cancer in 1926 were 6,920, equal to a death rate of 1.46 per 1,000, which is greater than that of 1925. Much of the increase in the cancer death rates since the beginning of this century merely reflects an altered age-constitution of the population of London. When allowance is made for this alteration it appears that the number of deaths among females has decreased, while the deaths among males have increased but slightly.

Under the heading administration reference is made to the tuberculosis scheme of the council. An investigation of the after-histories of 1,510 adult patients treated in residential institutions in 1922 reveals that 48.6 per cent are now at work, 5.6 per cent fit for work but unemployed, 43.7 per cent unable to work, and 2.1 per cent unknown. In April, 1925, a scheme was put into operation for removing children from overcrowded homes containing a case of advanced phthisis. Up to the end of 1926 688 applications had been received and 324 children boarded out. There is now no waiting list for residential treatment either for pulmonary or surgical cases in children. The extensive work of the council's chemical and bacteriological laboratories is reviewed. From observations made on visibility and retinicity there is no doubt that the smoke of London is an important and aggravating factor in screening off actinic light and in intensifying seasonal obscuration.

(To be continued)

### *HAM GREEN HOSPITAL, BRISTOL*

In Bristol, in the fourteenth century, there were three leper hospitals, and when leprosy became extinct no special hospital provision was made for infectious diseases for some centuries. In 1696 the guardians of the poor must have provided some accommodation for epidemic sickness, since Dover describes how, when spotted fever raged in Bristol, he visited from twenty to thirty patients a day, besides then poor children taken into the workhouse. During the cholera of 1849, and the typhus of 1865, the guardians provided isolation accommodation, a duty which

they shared with the sanitary authority in 1886. The sanitary authority's share was at first two temporary wooden buildings in St. Philip's Marsh, then in 1892 a hospital was established at Novis Hill, primarily for small-pox. But soon after, in 1894, a fine Georgian mansion, called Ham Green, with estate of ninety-nine acres, situated on the Somerset bank of the Avon near its mouth, was purchased by the Bristol city council, and on this estate a modern isolation hospital containing seventy-six beds was built and opened in 1899. The estate was enlarged to 92 acres in 1919 and 136 acres in 1920. The latter purchase included a farmhouse with outbuildings, and the total estate now covers 327 acres. The farm supplies the hospital with milk, butter, eggs, a considerable amount of meat, and all vegetables. There are fine fruit gardens, and a lake on the estate supplies water for domestic uses other than cooking and drinking. The original seventy-six beds have been increased from time to time, fifty-eight beds were added in 1904, with space allowed for 200 fever beds in emergency. There are fifty-two beds for advanced cases of tuberculosis, but in recent years, on one or two occasions, these beds have had to be commandeered for diphtheria and scarlet fever epidemics. The need for extension of "fever" accommodation was thus evident, and the Ministry of Health approved of the plans for fifty-six additional beds. The opening of the newest extensions was described in our issue of June 25th (p. 1160).

The original hospital consists of four ward pavilions and two isolation pavilions, providing seventy-six beds, together with administration building, laundry, electric light station, and lodge. In 1894 four more pavilions, accommodating sixty extra patients, were added, the administration building was extended, the discharge block was built, and also a water tower. The latest extensions include a two-story pavilion, containing fifty-six beds, a new administration building for twenty-four additional staff, and kitchens with offices. The new ward pavilion consists of a main entrance with vestibule and central hall, out of which the male ward (ten beds) opens on the east side and the female ward (fourteen beds) on the west side. There is a south wing containing four single-bed isolation wards on the ground floor, each opening on to a covered verandah, which extends along the west side of the south wing. At the end of each wing is a sanitary block. On the south side of the east and west wings are covered verandahs, twelve feet wide, communicating with the wards, so that all the patients' beds can easily be moved on to the verandahs if the weather is suitable. In the centre of the building is the nurses' duty room, so situated that complete observation is obtained over all the wards.

The new wards present several novel features compared with the older building. They are built asymmetrically. There are four more beds on the female than on the male side, as it is found that the admission of females is always in excess of males. The isolation block is attached to the main ward and will be nursed by the same nurses, the duty room being so arranged as to enable the main and isolation wards to be under observation through inspection windows by the provision of glass partitions between each isolation cubicle. The cubicles are intended for the nursing of doubtful cases, or cases where the patient may be suffering from two diseases simultaneously. It used to be thought necessary to nurse such cases in a separate block with a separate staff, but it is now believed that infectious diseases (with the possible exception of small-pox) cannot be airborne except through about half a dozen feet. In fact, if a second disease is introduced by accident into a ward of patients, it will not spread if free ventilation is practised by open windows, in addition to elaborate precautions to prevent the carriage of infection on the hands of attendants. The new buildings are constructed of red brick with Bath stone dressings. The designs were prepared in the office of the city engineer and the construction was carried out under the personal supervision of Mr. H. W. Harding, L.R.I.B.A., architect.

Ham Green Hospital has an additional interest in that the nursing staff has been for some years most satisfactorily protected from diphtheria by means of Schick's preventive inoculation. Prior to the introduction of this method in

1922, 20 per cent of the new staff were attacked by diphtheria, no case has occurred among the staff for over a year. This is a result of which Dr D S Davies (medical officer of health for Bristol) and Dr B A I Peters (resident medical officer) may well be proud.

#### MENTAL RESEARCH

The annual report of the Laboratory of the Joint Board of Research for Mental Disease at Birmingham for the year ending March, 1927, is prefaced by a tribute to the late Sir Frederick Mott, its honorary director, who passed away last July in the Birmingham General Hospital as a result of a cerebral thrombosis which occurred during a train journey from London to Birmingham. Sir Frederick Mott, the report recalls, accepted the directorship of the board following its inauguration in 1922, and devoted his energies to the establishment of a research laboratory at Birmingham in connexion with the Rulery and Hollymoor Mental Hospitals, on lines similar to those at the Maudsley Hospital in London. Work carried on under his direction included the determination of iodine in thyroid glands and the correlation of mental and physical conditions. A new method of determining the basal metabolism of patients by means of a chamber was devised and the apparatus was installed at Hollymoor. Other investigations begun were into the individual reaction of patients to certain problems connected with subacute and chronic infections, into the relation of the enteric group to the immunological processes as having a possible bearing upon endocrine activity, and into chronic sepsis in its association with focal lesions elsewhere, with possible toxic effects upon the nervous system. Work was carried on under his direction in the wards of the hospital, especially with regard to the treatment of general paralytics by trypanamide, the results were assisted by laboratory examination of the body fluids. He gave up much of his time to the teaching of the medical officers of the institutions, all of whom obtained the diploma of psychological medicine, he was also lecturer in morbid psychology at the University of Birmingham in 1923-24-25, and was about to continue in 1926. The great loss to the world of such a widely experienced neurologist, especially in the field of research in mental disease, could not be estimated. The laboratory director, Dr F A Pickworth, was appointed to the directorship of the board last October, and the work subsequently carried on has been planned for some time to continue on the lines initiated by Sir Frederick Mott. The work on basal metabolism has necessitated the investigation of the basal rate of normal subjects, and the results have been collected in a paper presented to the Royal Society by Professor Haldane, and published in its *Proceedings*. Serological agglutinations to the typhoid dysentery group of organisms have been made as a routine on every patient in the hospital, and serological agglutination curves of animals have been determined following treatment to elucidate the atypical agglutination reaction of the patients. Material from chronic septic foci has been investigated for the type of organism and the histological appearances of the tissue. Many patients have been examined for the alteration of the permeability of the brain membranes. The post mortem appearances of the nasal sinuses have been carefully studied and further cases of nasal sinus disease discovered. One case showed a long-standing perforation of the sphenoid sinus into the pituitary fossa. The pituitary was surrounded by a mucinous septic fluid, and there was evidence of considerable extension subdurally of this septic process.

## Scotland.

#### THE PINEL CENTENARY IN EDINBURGH

In commemoration of the centenary of the death of Philippe Pinel, a laurel wreath was placed, on July 22nd on his bust, which is built into the archway of the Royal Edinburgh Mental Hospital at Morningside. Sir H Arthur Roe, chairman of the General Board of Control for Scotland, who presided at the ceremony, referred to the magnitude of the change in psychiatry which could be traced back to

the labours of Pinel in France. Dr H Calm of Paris, commenting on the historical friendship between Scotland and France, said that, though Pinel had died in 1826, the statue to his memory in Paris was only erected in 1883, while the bust in Edinburgh had been placed in position as early as 1838. Dr Hamilton Marr, president of the British Psychological Society and one of the vice presidents of the Section of Mental Diseases at the Annual Meeting of the British Medical Association at Edinburgh, compared the aspirations and achievements of Pinel with those of Lister.

#### EDINBURGH DENTAL HOSPITAL

The new buildings of the Incorporated Dental Hospital and School were opened on July 15th by the Right Hon. Sir Francis Doyle Acland, chairman of the Dental Board of the United Kingdom. Dr William Guy F R C S, dean of the school, presided. In declaring the buildings open, Sir Francis Acland said that the work of the Dental Board fell under two chief headings. The first was to improve the importance of dental health as a basis of general health and of national efficiency, and the second to take care that the means for securing dental health were as good as it was possible to make them. The Board was using the annual fees paid by the dentists admitted to the *Dentists' Register* since the passing of the 1921 Act in order to give to others a better training. He believed that more dentists would have to be trained as the enormous importance of dental health became better appreciated. The reputation of the Edinburgh Dental School showed that the scientific and practical aspects of dental education were combined in it in an unusually thorough way. Only in those districts where, in addition to a fresh supply of competent dentists, the needs of the dental hospital were fully met could the claim be substantiated that the dental needs of the people were properly provided for. Among such districts he hoped that Edinburgh might always take a prominent place. After declaring the buildings open, Sir Francis Acland presented the prizes for the session. The new buildings, which have a handsome frontage in alignment with the other buildings in Chambers Street, stand in front of the old Dental Hospital, which has not been demolished. The present extension has cost £17,000, and has been carried out with the help of the Dental Board, which contributed £5,000 towards the new buildings, and £1,000 towards their equipment. A dinner to commemorate the official opening of the new buildings was held the same evening and Dr William Guy, who presided, remarked that he had seen the Edinburgh Dental School grow from the time when it occupied a single room at No 30 Chamber Street. From there it had migrated to Lauriston Lane and occupied a saloon; next it returned to 31, Chambers Street where the Dental School shared a building with the Eye Dispensary, nor it had a school in the city of Edinburgh, in which the facilities were fully adequate to the complete instruction and education of a very large number of dental students, he believed that the men who obtained there the highest at the Royal College of Surgeons need not fear comparison with men who had received their education anywhere else.

#### CHEMISTRY IN THE PROGRESS OF MEDICINE

The Society of Chemical Industry held its fortieth annual meeting in Edinburgh last month. It was attended by about 250 delegates who were received by Lord Provost Stevenson on behalf of the city and by Professor Sir Thomas Hudson Beare, dean of the faculty of science on behalf of the university. The dean remarked that in 1912 it had been decided to house the chemical department of the university in a new building. Although this project had been delayed by the war the university had now embarked on an expenditure of about a quarter of a million sterling for this purpose. The debt for the building of the great chemical laboratory at West Main had been practically extinguished already. The question of degrees in science had also been considered and they had been reorganized under a new ordinance. At the meeting followed Mr Francis H Carr C B E, president and delivered an address entitled 'Chemistry in the progress of medicine'. Pure and applied chemistry were, he said,

equally necessary for progress in the field of chemical industry, and medicine was dependent upon chemistry in some important respects. One of the principles of medical treatment to-day was to help the body to produce its own curative agents. The effect of most of the medicines employed was not directly to cure, but to relieve symptoms and to secure rest, and thus enable the body to overcome disease. Among the older drugs some, such as emehona and ippecuanha, acted directly as curative agents, and the lecturer directed particular attention to these and to the numerous synthetic chemotherapeutic substances which now found a place in medical treatment. Enough was not yet known regarding the physiology of living processes to enable a reasoned plan to be framed on which to search for chemical agents that would restore the unhealthy body to its normal condition. The chemical constitution of adrenaline, thyroxine, and histamine had been ascertained, and these compounds could be prepared synthetically, but the methods of their release from the glands which contained them was not yet known, nor even whether they could exert their action without first being built into more complex molecules within the body. In spite of numerous investigations on the production of antibodies, when bacteria or foreign proteins were introduced into the body, nothing of their real chemical nature was known. The fact that a chemical substance would destroy micro-organisms in a test tube was no guarantee that it would be of use in combating infection by the same organism in the living body. It was evident that the best therapeutic agent was likely to be the one which most nearly imitated nature, and it now appeared probable that the body by no means played a passive part in the effects thus obtained, as suggested by phenomena seen in the case of the action of salvarsan. Dale had pointed out that certain parasites in the blood of a mouse became more resistant to arsenical drugs after the animal had received a number of incompletely effective doses, whereas if the organisms were then transferred to rats they again became susceptible. Other observers had shown that a period of time elapsed between the injection and the development of the maximum toxic action, associated probably with oxidation-reduction processes in the cells. There was no reason to suppose that a dye produced any particular antiseptic effect because of its colour, many colourless substances would doubtless act as well, but the antiseptic property could not be so readily detected in them. Thus Bayer 205 and Fournier 309—colourless complex mer derivatives allied to dyestuffs—had a remarkable therapeutic action in sleeping sickness. Although effective *in vivo*, they had little action on trypanosomes *in vitro*, thus indicating that the host participated in the destruction of the parasite. A property which effective chemotherapeutic agents should possess was that of long-continued action. Such effects had been demonstrated in the case of bismuth. More effective therapeutic agents had been discovered against protozoal than against bacterial diseases, for experimental work in the former had been easier and less reliance had been placed on experiments carried out purely *in vitro*. The fact that a suitable animal test might lead to the discovery of useful therapeutic substances was shown by "plasmoguin," a quinoline derivative allied to quinine and most effective in the destruction of the crescent forms of the malarial parasite. The test animal used in this particular instance was the canary, infected with the parasite of avian malaria. The lecturer believed that future advances in chemotherapy lay in the direction of biochemistry, and needed more effective contact between workers in chemistry, bacteriology, physiology, and clinical medicine, less reliance must be placed on experiments *in vitro*, and adequate animal tests must be followed by extensive clinical trials.

#### ANNUAL REPORT OF THE SCOTTISH BOARD OF HEALTH \*

##### Water Supply

Under water supply it is satisfactory to observe that in terms of the last of a number of schemes entertained by the town council of Perth for the water supply of the city, as confirmed by Parliament last year, a chlorination plant

for the River Tay water is to be installed to the satisfaction of a person approved by the Scottish Board of Health, while the engineer in charge and the bacteriologist retained by the council must likewise have the Board's approval. Examples of outlying towns or villages which, though wishful to improve their supplies, have been deterred by prohibitive costs, are also cited in this section.

##### Veneral Disease

From a tabular analysis covering a five-year period it emerges that syphilis, soft chancre, and mixed infections in males are showing a steady decrease. New cases of gonorrhoea in males increased up to 1924-25, but have since declined. In women new cases of syphilis and soft chancre are diminishing in number, but gonorrhoea in 1925-26 showed a rise of 30 per cent, ascribed in part to the opening of four new treatment centres. The percentage of defaulters is slowly growing less. Edinburgh and Glasgow have each appointed a visiting nurse almoner to deal with these persons.

##### The Hospital Question

Reference is made to the report of the Hospital Services (Scotland) Committee, submitted in January, 1926. The committee, under the chairmanship of Lord Mackenzie, made certain recommendations in an attempt to secure, by co-operation all round, and not least between the voluntary hospitals and the local authorities, a continuously adequate hospital service. Such co-operation the Scottish Board of Health has always sought to encourage, and arrangements in this spirit seem likely to fructify at Stirling and Falkirk, where it is in contemplation to include a maternity wing in the proposed re-creation on a new site of the two general hospitals concerned. The enlightened policy of the parish council of Glasgow, which has raised Stobhill to the rank of a first-grade hospital, placed its surplus beds at the disposal of the Glasgow Royal Maternity Hospital, and opened its doors to receive encephalitis lethargica from every part of Scotland, is another pertinent instance. The town council of Aberdeen, anticipating Pool Law reform, are entering into a contract with the parish council to take over the Pool Law hospital and treat all Pool Law patients. The Scottish voluntary hospitals, too, are consolidating their position. The Northern Infirmary at Inverness is to be reconstructed, and general infirmaries in Glasgow and Edinburgh are erecting auxiliary hospitals. These various enterprises are all to the good, but there is still a shortage of general hospital beds in Scotland, and a national organization on the lines recommended by the Mackenzie Committee remains a pressing need.

##### School Health Administration

There were approximately 823,028 pupils in average enrolment in 3,458 State-aided schools in Scotland, in all of which there was systematic medical inspection. The total number of children in selected age groups examined during the year was 254,570. In addition, 209,574 special examinations were made. The total examinations were 464,144, an increase on last year.

The nutrition of 61 per cent of the children examined was below average, of 13 per thousand very poor. Marked enlargement of tonsils and adenoids was noted in 4.9 per cent. At least 6.5 per cent of the children in school have defective vision requiring glasses. Heart defects, organic or functional, were found in 1.4 per cent. Actual vermin were discovered on the heads of 2.16 per cent. The short hair now common should make it easier for parents to prevent infestation. The school medical officer of Roxburgh, however, suggests that since bobbed hair needs less attention it probably gets less. Mild infestation among girls in Roxburgh is increasing. Owing to the dispute in the coal-mining industry a fairly extensive scheme for the feeding of school children was adopted in most colliery areas.

Defective vision was treated in all districts. Renfrewshire education authority have introduced special classes for the blind of school age. Orthopaedic treatment is provided by a few authorities. In Glasgow two medical gymnasts are employed full time. Orthopaedic appliances were

supplied to 112 Glasgow children. Lanarkshire children received treatment at the Glasgow Royal Hospital for Sick Children and elsewhere.

#### The Insured Sick

The district medical officers of the Board, who act as referees and consultants, have now been at work for over five years and in that time 83,045 persons have passed through their hands. Three studies, based on this field of work, which are presented in the report, furnish material for estimating the medical significance of the system of national health insurance. The study of urban versus rural conditions as affecting the incidence and causation of incapacity reveals a higher proportion of lung tuberculosis in rural than in urban areas. In both areas rheumatism, rheumatoid arthritis and cardiovascular disease increase as incapacitating factors in each successive decade. The weight of anaemia, in the ages at which it occurs, appears as approximately equal in rural and urban areas. This equality is, however, fallacious, since 70 per cent of the rural cases were domestic servants who had given up situations in towns on becoming chlorotic and had returned to their homes in the country in order to recuperate. The seasonal incidence of rheumatism and non-tuberculous pulmonary disease is not dissimilar in urban and rural areas during most of the year. From October onwards, however, both conditions show a fall in rural areas but a rise in the towns. The study of the work of the district medical officer in a consultant capacity exhibits the variety of the circumstances in which he can aid the insurance practitioner. His work is of most value in the rural areas, where the sense of medical loneliness is so often felt, especially in cases where improvement is slow and friends are apprehensive. A note on mitral disease following rheumatic fever is appended to this study. The third study is based on cases of bronchitis referred in 1925. The weight of bronchitis among all forms of illness referred was represented by 8 per cent. It is questioned whether bronchitis alone results in a permanent nil working capacity unless in a small minority of cases. Except during acute or subacute attacks such patients are usually capable of some form of employment. It is admitted, however, that the disease entails a lowered working value. Of 495 cases of bronchitis in the district 297 were in the heavy trades, of whom 199 were miners, 57 general labourers, 18 metal workers, and the remaining 23 distributed among the occupations of iron and brass founders, woodworkers, quartermen, engineers, dock labourers, builders, blacksmiths, and brickmakers.

#### Other Subjects

Among other subjects of interest are influenza on St. Kilda, maternity service and child welfare, supervision of the food supply, including the Milk and Dairies (Scotland) Act, 1914, veterinary inspectors, dairy by-laws, Milk and Dairies (Scotland) Order 1925, milk-borne infections, meat inspection, humane slaughter, and preservatives in food, the handling and storage of food, national health insurance in its manifold aspects including dental and ophthalmic benefit, anaesthesia, mileage, and dispensing, Poor Law administration, old age pensions, and the welfare of the blind.

#### Conclusion

The foregoing are some of the more outstanding features of an annual report which, while conveying appropriate information on the departmental side, has at the same time a strong medical interest. The *res medica* is by no means a new topic in the reports of the Scottish Board, but it seems as if in that for 1926 it had emerged into special prominence. This is great gain. There is in these days a good deal of talk on the subject of health propaganda which has for its object to shepherd the masses along good ways of living. Any enterprise so directed is useful, and should be encouraged, but there is a not less important field of health propaganda, which is worthy of cultivation, among educated and well-informed people whose views or convictions on medical questions would influence or guide the trend of opinion in the country. To the perusal and attentive study of such the Board's report is commended. It will show them how medical thought is

moving, indicate the lines of administrative advance which are most vital at the present time, and will, if they are public spirited citizens, whether medical or lay, enlist their cordial co-operation in accredited schemes for the promotion of the public health.

## Ireland.

### REGISTRATION OF DIRECT REPRESENTATIVES

#### MEDICAL PRACTITIONERS ACT 1927 (IRISH FREE STATE)

NOTICE of election is issued for two direct representatives of the medical profession resident in the Irish Free State to be members of the Medical Registration Council. Any registered medical practitioner resident in the Free State is eligible to be nominated as a candidate, and every registered medical practitioner resident in the Free State is entitled to take part in nominating two candidates but no more. Every nomination paper must state the names, address, and registered qualifications of the candidate nominated. It must be signed by not less than three registered medical practitioners resident in the Free State. Nomination papers may be obtained from the Returning Officer, Room 242, Department of Local Government and Public Health, Upper Morrison Street, Dublin. Votes cast by voting papers must be received by the Returning Officer not later than August 22nd, 1927.

#### Dr P. J. Powlette's Candidature

Dr R. J. Powlette has consented to become a candidate as a direct representative of the medical practitioners in the Free State. He is one of the best known medical men in Ireland and for the past twenty years has given very freely of his time to the interests of the profession. He has been selected on several occasions by the joint medical organizations to represent the interests of the profession on all commissions of a medical nature. Through his extensive knowledge of medical matters generally and a commanding personality, he has been responsible in recent reports published by commissions and committees for recommendations of outstanding importance with regard to public health matters and the profession. Dr Powlette has been an active member of the British Medical Association, and was some years ago president of the Leinster Branch. He is a member of the Irish Medical Committee and of the council of the Irish Medical Association. He was also a member of the Irish Public Health Council in 1919, and of the Committee of Inquiry on National Health Insurance on the Public Medical Services in 1924. Dr Powlette is assured of the support of all medico-political organizations in Ireland. It is hoped that medical practitioners who will receive voting papers, will fill them up at once and forward them to the Returning Officer.

## Correspondence

### THE INTERNATIONAL CONTROL OF DRUGS OF ADDICTION

SIR—In the JOURNAL of July 16th (p. 167) an account is given of the attempt to secure the international limitation of morphine and other drugs of addiction to legitimate purposes. It is now generally recognized that the use of opium, either for eating or smoking, is responsible for relatively little harm at any rate in the West. It is only after the chemist has extracted the alkaloid morphine that the European falls a victim to the vice.

Most European countries prepare morphine from opium, but under the international convention this is done only as it is required for the legitimate purposes of medicine or for export to other countries under strict supervision. Unfortunately this convention was so worded as to leave plenty of loophole for the manufacturer to evade these restrictions, morphine derivatives which are not known to lead to addiction can be exported freely. As an example of my meaning I may say that it is known at the present time that certain Continental manufacturers are

exporting a new compound of morphine and benzene, a product which is not known to be a drug of addiction, and which, therefore, can be manufactured and exported like other non-addiction drugs. If this substance is treated with potassium carbonate the morphine is readily regenerated, and so it happens that morphine is easily transferred from country to country. No doubt the League, through its experts, will shortly be able to show that this substance can lead to addiction like morphine, and restrictions will be imposed, but a new substance will then doubtless be forthcoming to replace it. These facts point to the advisability—if this should be a practical policy—of controlling the growth of the opium poppy in Turkey, Persia, and other places—that is, of limiting the supply of material from which the alkaloid is manufactured.

The danger to Europe and America, however, does not lie even with morphine, but with the much more dreaded substance, the direct derivative known as heroin. This substance acts with rapidity and does not constipate, or does so only to a negligible extent. It is the "perfect" narcotic for the social and sexual pervert. It is not perhaps properly recognized, even by medical men, that heroin acts also as a powerful aphrodisiac, exaggerating pelvic reflexes for several hours after injection or snuffing. It excites the male in this respect much as cocaine excites the female.

Many thoughtful people who have followed the trend of modern addiction are convinced that evidence shows that heroin addiction is spreading in spite of all preventive measures. They fear that it is likely to become, in Europe as a whole, as serious a menace to social life as it is in Russia and America. At present the evidence afforded by the committee of the Ministry of Health sitting under Sir Humphry Rolleston has made it clear that England is relatively free from this vice. Nevertheless the "narcotic" is believed to be an increasing product of our civilization, and it is especially these people who fall ready victims to heroin. The soil is ripe, but the opportunity, knowledge, and material are not easily available.

On the Continent I have been left with the impression that experts are gradually becoming convinced that prohibition of the manufacture of heroin is the best and perhaps the only method of destroying this evil, a principle which I believe has already been adopted in America. In England, where there is no immediate menace, physicians freely prescribe heroin, and some distinguished physicians assert that for certain purposes its usefulness cannot be replaced by either codeine or morphine. While I do not in any way wish to grant this teaching, it appears to me that the time is coming when we shall have to choose between two policies—either to encourage the manufacture of heroin by still prescribing it, or to range ourselves with the United States and some European countries and adopt the policy of complete prohibition of heroin in this country for any purpose.

The menace on the Continent is already very real, and the medical profession in this country may be required to make a decision, sooner or later, as to whether the safety of and benefit to the British Empire which may be attained from the complete prohibition of heroin may not be greater than the palliative relief afforded to a few patients, which some of us think may be obtained with codeine or morphine—I am, etc.,

### THE PROPOSED NEW HOSPITAL POLICY

SIR,—Mr Hey Groves, in his address published in the *JOURNAL* of July 23rd (p. 151), advocates the support of the hospitals from the rates and taxes. I agree that it is doubtful if voluntary aid will be sufficient to meet the demand for hospital treatment much longer, as the voluntary hospitals are now living such a hard financial struggle. But, recognizing the fact that voluntary support comes from those best able to pay, and who might feel they ought to do so, I think we should be glad to postpone the substitution of State aid for it, as this would necessitate an increase of the income tax, which would levy contribu-

tions from those by no means wealthy, as well as the rich, and, I fear, if the hospitals were also supported out of the rates, from even the poorest classes, which I think would be most undesirable. Neither do I think any further demand should be made on this class, in the form of insurance, for the support of the hospitals.

It may be suggested that a compromise would be a wise policy—that the charitable public should give all they can and the deficit be made up by a State grant. But if the charitable public knew that the State would make up any deficiency would they give at all? Are they not likely to leave all support to the State? It seems to me that the hospitals must be supported wholly by charity or wholly by the State. I do not refer to occasional State grants to help hospitals in exceptional financial difficulty, but to permanent aid.

I cannot agree with Mr Groves that the hospitals at present supported by voluntary contributions must be supported by the State in order that the standard of efficiency for treatment, teaching, and research may be raised, as I consider that the voluntary hospitals are very well equipped and very efficient, even having regard to the requirements of the present day.

As to Mr Groves's proposal to scrap existing city hospitals and build new ones in the country—for many patients treatment in a country hospital with open-air wards is, of course, clearly indicated, not only as it is valuable in all cases of tuberculosis, but also, I understand, in cases of heart disease in childhood, and it is an advantage in the treatment of many forms of chronic disease. When patients require very prolonged hospital treatment, as orthopaedic cases often do, it is also clearly indicated. But I do not think it is necessary that a patient who will only be confined in hospital a few weeks, with a broken leg, or an acute attack of pneumonia, or has required operation for some acute abdominal condition, or comes into hospital for a radical cure of hernia, should be in a country hospital. If it is suggested that a country air is an asset in treatment then even those whose stay in hospital is only short should have it, I would point out that it is such a subsidiary factor in the treatment of these cases as to be really negligible. It is a distinct advantage to have patients in the city hospital, as they are there readily accessible to the visiting staff, to their relations, and to the students. To scrap these city hospitals and replace them by country hospitals seems to me an unnecessary and very regrettable waste of money, which should not be incurred, even if the money to build new hospitals were provided by the rates and income tax, and not out of charity funds.

Certainly hospital extension might with great advantage be carried out by the provision of these open-air wards in country hospitals. Such cases as would materially benefit from treatment in them could be shifted out to them, and thus beds left free for cases suitable for treatment in the city hospital. No doubt if we rebuilt many of our city hospitals we should considerably improve their construction, but really they are too good to be scrapped, even though the site of their sites, as Mr Groves suggests, would help in some degree to pay for the erection of the new buildings.

One reason given by Mr Groves for abandoning the two large hospitals in this city (Bristol), and erecting one hospital large enough to receive all the cases, is that it would allow medical and surgical cases to be segregated into subsections, each under the care of one physician or surgeon, so that there would be departments of orthopaedic surgery, urogenital surgery, diseases of the rectum, the nervous system, and the heart, and so on. I agree that such increased specialization would be an advantage to the patients, for obviously the man who concentrates on the diseases of one region of the body, if he has sufficient cases to give him a wide experience, is able to make better diagnoses and provide better treatment than one with a less specialized knowledge. But the question is, Would this system work? The difficulty would be that when medicine and surgery had been subdivided into all these sections, and every physician and surgeon transformed into a specialist in a subsection, a city of the size of Bristol (or even a larger one) and its surrounding

may not supply enough cases of these special affections in private practice for these very numerous specialists to make a sufficient income. If it is suggested that this difficulty would not arise, because in future all members of the staff would be paid a sufficient salary for their hospital work by the State or municipality to make them independent of private practice, then the question will come: How are the members of the community who can pay for their treatment by these specialists to obtain their services? Is it proposed that they should become wholly Government officials, undertaking both hospital and private practice for their State salary, so that in future the public would only have the services of hospital specialists as paid State officers?

I think it is quite clear that a physician or surgeon taking over the charge of one of these new departments must devote his whole time to that line of work. A surgeon in charge of, say, a genito-urinary department in which were treated all such cases in a large city, would have to devote the whole of his hospital work to this department, and hence would have to confine his private work to that line of practice also, for all his hospital experience would only be required in that department of work. But what work will be left for the general physician and surgeon to do that will ensure him sufficient private practice? Would he become extinct?

This proposal to break up medicine and surgery into minute sub-sections and its effect on the general physician and surgeon, must also be considered in its relation to the teaching of students. The present plan of clerking and dressing for certain members of the staff would have to be abandoned, for there would either be no general physicians and surgeons, or their supply of cases would be too limited to teach from as the creation of all these special departments would leave very few cases for the general physicians and surgeons. The student would have to obtain his clinical knowledge by attending all the new departments, but as they would all be working separately he would have a very limited part of his curriculum to give to each. What would be the result on his training? It seems to me that the whole matter needs the most careful consideration—I am, etc.

BRISTOL, JULY 31st.

CHARLES A. MORTON

SIR,—I have read with great interest in the JOURNAL of June 23rd (p. 131) Mr. H. V. Croves' presidential address—a powerful appeal for the better organization, co-operation and co-ordination of our hospitals, the crying need for their development as one service. I can quite appreciate his impatience with the present system, or want of system, and his irritation at the very serious waste of opportunities.

I have no desire to re-open the controversy as between voluntary and State hospitals, but I cannot help thinking that Mr. Croves has overlooked the report issued six years ago, of the Voluntary Hospitals Commission. This report drew attention to the points so eloquently stated in Mr. Croves' address and suggested a system of local voluntary hospital committees and where necessary joint committees of these local bodies, for the better organization of the voluntary hospitals of any area. It pointed out that all that was needed was the active and willing co-operation of the hospitals.

A conference with a view to forming such a joint committee for Bristol, Somerset and Wilts was held in Bristol four years ago, but owing to the attitude of the two Bristol general hospitals the whole scheme aborted. I have no wish to pillory Bristol. I merely mention this instance to show that it is not the voluntary system that is at fault but the want of vision, the conservatism, the individualism, the parochial spirit of some of the governing bodies concerned.

It is quite possible that the methods to which resort has had to be had to obtain funds for these institutions have fostered the spirit of detachment. It is local contributory schemes and hospital Sunday with their wider appeal to the wants of the area and not of any particular institution should be some remedy for the disease. The

more general the practice of promoting hospital funds for the district and not for an institution the better the chance of getting adopted a policy of co-operation.

But I believe that the most powerful force at our disposal to bring about the reform Mr. Croves calls for is a carefully considered and agreed action of the medical profession in the districts concerned and this can best be obtained through the organization of the British Medical Association.

If a meeting representative of all the medical men in the district would discuss Mr. Croves' paper apart from the question of voluntary or State support would agree on a policy and would bring it to the notice of all authorities concerned and press it I have sufficient faith in the power of our profession to feel confident that in the end they would get their way—I am, etc.

BRADFORD on MON. JULY 24th

C. E. S. FLEMING

SIR,—I congratulate Mr. H. V. Croves on his bold statement of policy (July 23rd p. 131).

The change from voluntary to State control has increased the efficiency of the election system. Should the voluntary hospital system suffer a like change financial resources would be increased. Central control and greater co-ordination might be expected and an increase in the efficiency of this important national service.

So far the State has been most active in preventive medicine but it has made inroads into the domain of the voluntary hospital system. It is to be congratulated for the success which has attended its assumption of control in the treatment of venereal diseases.

That the voluntary hospital system has survived so long is a tribute to the excellence of its work but the time for change is ripe if only for the reason that shortage of funds is hampering the work—I am, etc.,

C. GIBSON

WIDEN, JULY 26th.

#### SALICIN AND SALICYLATES IN THE TREATMENT OF INFLUENZA

SIR,—I am sure all general practitioners must be greatly encouraged and inspired by the excellent address of Mr. E. B. Turner before the Metropolitan Counties Branch (JOURNAL, July 16th p. 93) on the clinical and therapeutical aspects of influenza since 1839 and on treatment by salicin. I have had somewhat similar experiences since 1890, the only difference being that my results were better with sodium salicylate in big doses repeated frequently than with salicin. This may be accounted for by two variables. When at the meeting of the British Medical Association at Edinburgh in 1893 Dr. J. J. Reid a paper on chorea, he mentioned the fact that nearly all his cases in the Great Ormond Street Children's Hospital in London had rheumatic nodules on the hands or feet. The late Dr. I. J. Reid at Steven was sitting next me at the time and I asked him if that was his experience in his Glasgow wards and he said, "No." On returning to Glasgow we went over a number of cases in the various hospitals, and privately and did not have the same experience. Later in the year we were both in London together and Dr. J. J. Reid verified his statement by showing his cases in Great Ormond Street. Over even the short distance of 100 miles we evidently have these race differences and this accounts in a great measure for our different experiences.

One of my teachers in medicine was great on salicin in rheumatism 20-grain doses every two hours. I was not long in general practice till I found that sodium salicylate responded better to the salicylates than to salicin and my experience was the same in epidemics of influenza. I agree with Mr. Turner's remarks on arthralgia and rheumatism given in his address. In regard to big doses I have given 60 grains of sodium salicylate at one time. The common practice of an Edinburgh consultant in the epidemics varied from 10 to 20 grains and he was not at all different in treatment. I had not my own experience from the very beginning. I was a poor lad none till later in the disease and then I lasted for an indefinite period. I am

with a friend an epidemic in the Midlands of England which was very much worse in type and in mortality than anything I had seen in Scotland. In an epidemic I saw in Barcelona in Spain the type was gastro-enteric, not very severe, and was followed by few sequelae. I think Christison was right when he characterized rheumatism as a form of exorating malaria or Roman fever, and influenza seems to be similar, since the products of the *Salix alba*, or witch willow, act very satisfactorily in both conditions—I am, etc.,

JAMES CRAIG, L R C P and S

Glasgow, July 16th

### THE EPIGLOTTIS IN RESPIRATORY OBSTRUCTION UNDER ANAESTHESIA

SIR,—Mr H Mortimer Wharry's account of the epiglottis in respiratory obstruction under anaesthesia (*BRITISH MEDICAL JOURNAL*, May 21st, p 914) is of considerable interest. In the *JOURNAL* of August 25th, 1923, Mr Wharry described in detail a case of epiglottic obstruction of the larynx, in which the patient became "completely cyanosed," "the epiglottis was entirely devoid of cartilage, and was of the consistency of a soft piece of wash-leather. It was lying right over the larynx, and in tight contact with the posterior pharyngeal wall, to which it was adhering by means of sticky mucus. It was thus acting as a valve, permitting a little air to escape from the chest, but none to enter. On hooking the epiglottis forward with my finger the patient took several deep breaths and became quite pink again."

In the corresponding columns of the *JOURNAL* for February 23rd, 1924, is a contribution on the same subject, entitled "Prevention of death under chloroform anaesthesia," by Lieut-Colonel F J Palmer, R A M C (Assam). He states therein "respiration fails first owing to the epiglottis sagging back and occluding the upper aperture of the larynx; forcible attempts at inspiration may lead to its rupture." "I am not prepared to state that all cases of chloroform emergency are due to this cause, but it is my belief that the overwhelming majority (probably 80 per cent) are. I am of opinion that in every case, during chloroform administration, the respiration fails first, as the Hyderabad Commission stated, but that the interval between respiratory and cardiac failure, in the case of a feeble heart, is so short that the respiratory failure is overlooked and the death attributed to primary heart failure." He states that he made this discovery of obstruction of the larynx by the epiglottis some seventeen years before, and that subsequently, in seventeen years of surgical work under varying conditions, where chloroform was usually the anaesthetic of choice, he never lost a case from respiratory failure under anaesthesia.

As shortly before this I had been present at a case of death from respiratory failure under anaesthesia, I was much interested. A few days later I was looking on at an operation on a tonsillar growth (dysplasia). Soon after the gag had been placed in position respiration ceased. The throat was swabbed out, etc., and various expedients tried without effect. Rather diffidently I suggested a digital examination. I found the epiglottis impacted in the larynx, and on this occasion, on being pried up, it flew out with an audible click (this is the only time I have heard it "click" out). It was audible to those close to the patient's head.

Since then I have taken the opportunity, whenever any respiratory trouble arises under anaesthesia and is not immediately overcome, of making a digital examination of the epiglottis. Up to the present time the epiglottis has been found to be the sole cause of the respiratory failure, and, in all, I have now seen eight cases of this type. It has occurred with four different anaesthetists, during abdominal as well as throat operations, during administration of chloroform, and also when nothing but ether had been administered. I am led to believe that many deaths under anaesthesia may be due to this preventable cause.

Two factors appear mainly responsible in my opinion, and result in the actual occlusion: (1) change in the position of the epiglottis, (2) commencing inspiration. The

first consists in the epiglottis sagging back, and may result from falling back of the jaw, or the tongue, from swallowing before deep anaesthesia is completely attained, from relaxation of the extrinsic and intrinsic tongue muscles, or from disturbance of the epiglottis during swabbing. Commencing inspiration completes the misfortune by suction on the epiglottis. In several cases the epiglottis appeared to have been completely "swallowed" by the larynx.

The emptiness of the lungs minimizes the chance of the epiglottis being spontaneously freed. A little air may escape from the chest, but none enters. On artificial respiration no air can be heard passing in and out—a useful and suggestive sign, if somewhat sinister. One is easily led to believe that air is passing to and from the lungs when this is not the case.

A striking feature of epiglottic obstruction is the silence of the process. Before anything amiss is noticed the obstruction is a *fait accompli*. There is no sound of active respiration, no movement of the diaphragm with abdominal excursion, no convulsive effort. The patient goes from bad to worse, with increasing cyanosis and failing pulse.

Once the obstruction is relieved, provided this is done early, respiration starts immediately. The respiratory centre is undoubtedly strongly stimulated at first, and if the obstruction is relieved before the centre has reached the stage of depression no trouble is likely to be experienced from this cause. Where artificial respiration is necessary oxygen administered alone would, in my opinion, be sufficient, as carbon dioxide would not be required as a stimulant to the respiratory centre, and in cases where the centre is depressed would be harmful.

The chief difficulty in freeing the epiglottis is due to inaccessibility. Curved instruments, direct laryngoscopy, or swabbing may be necessary if digital manipulation fails. Pushing the jaw well forward or traction on the tongue will unfortunately not usually free it. The digital method described by Colonel Palmer is useful. Endotracheal anaesthesia rules out the possibility of this type of obstruction, but may not always be available where an anaesthetic is essential, and the obstruction may arise during the anaesthesia before the introduction of the catheter.

Occlusion by the epiglottis may play a part in asphyxia neonatorum, particularly the cyanotic variety, and further investigation in these cases may be instructive.

In considering respiratory failure under anaesthesia occlusion of the larynx by the epiglottis appears to have passed largely unnoticed. In my opinion this type of respiratory failure is more common than is generally recognized, and is probably responsible for a considerable proportion of deaths under anaesthesia—I am, etc.,

G H CRAIG, F R C S Eng,

Assistant Surgeon, Royal East Sussex Ho Spital.

St Leonards on Sea, June 5th

### THE DEFINITION OF BLINDNESS

SIR,—In the issue of May 7th (p 848) there is a reference to the definition of blindness. The matter has come up in Melbourne in very practical form. In the Royal Victorian Institute for the Blind those who are willing are paid the difference in rate between their earnings and what they would have received if they had not been blind. The definition of total blindness adopted by the Australasian Medical Congress of 1923 was not being able to count fingers at two to three metres and possessing no vision which would assist in an occupation.

It will be obvious that people with vision of 6/60 will be helped considerably in doing their work, even as supposed blind people. Consequently two classes have come into existence, at all events from a scientific point of view—those possessing 6/60 vision and those who are totally blind. In my opinion the earning capacity of the two differs considerably.

On the administrative side I do not think the matter is finalized at present, but the issue must be settled sooner or later—I am, etc.,

Melbourne, June 12th

JAMES W BURRETT

## THE GENERAL PRACTITIONER AND ANTE-NATAL WORK

Sir,—At Edinburgh, the Representative Body resolved

That it be an instruction to the Council to consider the Midwives Act 1918 in the interests of all concerned in ante-natal work.

In moving this I dealt very briefly with the ante-natal problem, only referring, in the order of their importance, to those concerned (1) the unborn child, (2) the expectant mother, (3) the general practitioner, (4) the public, (5) the certified midwife. It can be proved clearly that none of these are getting anything like a square deal.

1 and 2 The mother and child have to negotiate an entanglement of very inferior, still difficult, red tape before they reach the skilled services of a practitioner in emergencies, not infrequently too late to prevent the calamities most of us are too familiar with.

3 By the public health authorities the practitioner is deemed competent enough to deal with the grave emergencies arising before, during, and following the lying-in period but is harried from carrying on that very work, ante-natal, by which these grave emergencies might be anticipated, mitigated, or even wholly eliminated. Why do the health authorities fail to co-operate more closely with the modern practitioner only too willing to carry out this essentially preventive work? Why is the general practitioner—competent to do this work, willing, and in a favourable position to influence, not a few, but every expectant mother—excluded from this, his legitimate field of work?

4 Is the attendance of 25 per cent. (usually it is less) of mothers at these clinics, when financial provision is made for 100 per cent. attendance, giving the public a fair deal? Surely not, especially when this low percentage does not include the very poor mothers, the most ignorant mothers, but often the reverse. The profession could demonstrate to the public that a more efficient and fuller service could be provided at the same, or even less, cost, than the services established in many areas without the general practitioner being allowed to participate in any way.

5 From many midwives complaints come of pressure brought to bear upon them to undertake work which is in the sphere of medical practice, involving careful measurements, tests, etc., to arrive at accurate diagnosis.

I write to urge the presentation of the case by the rank and file of the profession to the Council of the British Medical Association, not too fully versed, it seems, in all the facts. The Representative Body means by the above instruction that the Council should press for the amendment of the 1918 Act, without which no advance is possible.

Surely every expectant mother—the poorer, the greater need—is entitled to have briefed for the protection of herself and child as early in the case as possible the services of a certified midwife and the medical attendant who will ultimately have to deal with any emergency which may arise?

Access to maternity and ante-natal clinics and the carrying on of the work there by all those members of the profession practising midwifery, supplemented by following the same ante-natal methods in their own consulting rooms, is the solution.

At the Representative Meeting, on the platform and elsewhere frequent allusion was made to the increasing menace to the very existence of private practice—not forgetting that this refers to private specialism of every kind as well as general practice—from the increasing number of public clinics and hospitals staffed by whole-time officials. I would add also from the increasing use of the so-called voluntary hospitals by all classes of the public, but to which the private practitioner, unless he is one of the privileged staff, has little, if any access, except in certain enlightened areas. The remedy must be "Reasonable access to all clinics and hospitals—save strictly teaching hospitals—for the private practitioner, whether general or specialist who is competent and willing to co-operate in bringing within the reach of his patient the best facilities for modern treatment."

This is too formidable a question to discuss further at the moment but that it is not beyond solution I am convinced, knowing that this principle has been put into practice in this industrial part of Kent (population 140,000) as regards all the voluntary hospital, the one Poor Law hospital, and also as regards part of the public clinics.

May I take this opportunity of correcting a slight but important misreport in the SUPPLEMENT of July 30th.

I said "I wished I could agree with Dr. Martin that if the general practitioner made himself efficient he had the solution of ante-natal work in his own hands", not that "I agreed with Dr. Martin". I venture to emphasize this by putting it that if one hundred per cent. of practitioners in Dr. Martin's or any other county made themselves one hundred per cent. efficient neither he nor any other medical officer of health could, if they would ( ), bring them into this important work, as the Act stands.—I am, etc.,

Dartford July 24th.

M W PENN

## BREATHING EXERCISES WITH MOVING ARMS AND MUSCULAR INHIBITION

Sir—May I be allowed to add a small quota to the correspondence on breathing exercises in the form of a reply to Mr. Paramore's letter of March 19-1 (p. 542)? I plead distance to excuse the lateness of this note.

The simple experiments which Mr. Paramore describes—for example palpating the pectorals, major muscle during abduction of the arm while lying—do not in my view bear the interpretation which he gives them. He writes "It is found that with and during the movement, as the pectoralis major is being extended (that is, elongated) its tone—its tension—that is, its state of contraction, progressively increases." (The italics are mine.) I agree that its tension increases but it is surely unwarrantable to deduce from this that the "tone increases" or that the muscle is in a "state of contraction". Surely the muscle is simply stretched passively by the movement of abduction of the arm and hence its tension increases. Similarly we may stretch a slack piece of rope by simple extension and so make it tense but it does not follow that the "tone" of the rope is different, or that it is in a state of contraction. I think that this explanation holds in all the examples which Mr. Paramore produces. In the case of the erector spinae the movements are obviously more complicated and opposing groups of muscles have to come into play simultaneously owing to the varying angles of inclination of the body. Again, in extending the leg the tension of the fascia lata is increased and it seems to me that on this account also the hamstrings feel more tense.

The arguments adduced by Surgeon Commander Hill in his communication of March 5th appear well founded and it is reasonable to suppose that in order to support the extra effectual weight of the raised arms various muscle groups have to keep the thorax and abdomen more rigid than normal, and he claims that the spirometer and x-rays confirm these statements.

Surely we cannot assume that the effect of raising the arms actively during breathing exercises has the same effect on the thorax as the passive movements in artificial respiration but Mr. Paramore in his third paragraph seems to make this a supposition. In artificial respiration the thorax cannot be actively and more rigidly fixed by contraction of other muscles, as Surgeon Commander Hill rightly claims, since the arms are raised during breathing exercises.

This explanation of Mr. Paramore's example therefore does not appear to be at variance with the theory of the inhibition of antagonistic muscles. He suggests that the inhibition is the exception and that active participation of opposing muscles is necessary for co-ordinated movement. The co-ordination may reasonably be explained on Hunter's theory of the sympathetic innervation of striped muscles.

According to Hunter (BRITISH MEDICAL JOURNAL vol. 1, 1922a) postural tone is due to contractile tone (omatic nerves) and plastic tone which is provided by non-medullated sympathetic nerves, innervating the "fixing" muscle fibres. On voluntary movement there is inhibition

of this postural tone, the new position is taken up by contractile fibres, and then the fixing fibres supply plastic tone to assist in maintaining the new position. This plastic tone is present not only in the muscles actively producing the posture, but also in the antagonistic muscles, and it is reasonable to suppose that there is more inhibition of contractile than of plastic tone in opposing muscles. Compared with the state of affairs in the moving muscles (where over-contractile tone is very obvious), there is relatively a preponderance of plastic tone over contractile tone in the antagonistic muscles. But this plastic tone in these muscles will not be evident (as is a contraction) on palpation by the hand. Co-ordination is thus provided, but the explanation of the tense feeling in Mr Paramore's examples is as I have outlined above.

The evidence for the reflex inhibition of antagonistic muscles is weighty, and a disturbance of this function and corresponding failure of co-ordination is more likely to be the explanation of the phenomena of the diseases mentioned by Mr Paramore than an active contraction of opposing muscles normally—I am, etc.,

ROBERT J GITTINS, M D

Friends Hospital Trust, C P, India

## Obituary.

SIR BRYAN DONKIN, M D, F R C P,

Late Physician to Westminster Hospital and a Commissioner of Prisons

WE announced with much regret last week the death, on July 26th, at his house in London, of Sir Bryan Donkin, at the age of 82. He had been in good health until comparatively recently, when his vigour began to fail.

Horatio Bryan Donkin was the son of a civil engineer. He was born at Blackheath, and there went to school. He entered Queen's College, Oxford, in 1862 as an open scholar and took a first class in Greats (classical). He attended St Thomas's Hospital and took the M B degree at Oxford in 1873. He proceeded to the M D in 1893, and was elected F R C P in 1880. He at first settled down in practice as a physician in London, and became attached to the Westminster Hospital (where he was lecturer on medicine) and to the East London Hospital for Children, Shadwell. He lectured also on medicine at the London School of Medicine for Women. On his appointment to be a commissioner of prisons and director of convict prisons he resigned these clinical appointments, and was appointed consulting physician in both instances. During his connection with the prison service he was a member of the visiting committees at the Borstal institutions, of the Royal Commission on Control of the Feeble-minded (1904-8), and of several departmental committees appointed by the Home Office. When he retired from the directorship he was appointed medical adviser to the Prison Commission. Afterwards he lived in retirement in London, but continued to take keen interest in matters relating to criminology and mental disease. He gave a course of lectures at the Maudsley Hospital on mental defect and criminal conduct, and delivered the Harveian Oration of the Royal College of Physicians in 1913, taking as his subject "The inheritance of mental characters." He received the honour of knighthood in 1911.

He was a frequent writer of articles, not only in the medical and psychological press, but also in the monthly reviews, and made many contributions to the *Times*. He took an active interest also in the prevention and treatment of venereal disease, and was one of the founders of the Society bearing that name. He held strong personal views on the subject, and did not always see eye to eye with some of his colleagues in the society. He was for a good many years a member of the British Medical Association, but never took an active part in its affairs. He was also an honorary member of the Royal Medico-Psychological Association.

Donkin, during early middle-life, and indeed beyond, was very well known in London, both to the profession of medicine and to biologists. In association with his friend Sir E Ray Lankester he was active in the investigation,

and on some occasions in the exposure, of spiritualistic methods. Intellectually in this matter, as indeed in all others, he was fearless and was not afraid to go where his observations and conclusions led him. The controversy was rather died down, but at the time to which we refer it was burning fiercely. Donkin was a clubbable man, he was particularly fond of the Swile Club, and followed its fortunes from Savile Row to Piccadilly.

Donkin married rather late in life, his first wife being a Polish lady. After her death he married again, an American lady, the widow of Mr Isaac Bites of Belfast.

## CHARLES CREIGHTON, M D

CHARLES CREIGHTON died on July 18th in the country village of Upper Boddington, Northamptonshire, to which he retired some years ago. He was born at Peterhead in 1847, graduated M A Aberdeen in 1867, studied medicine at Aberdeen, Edinburgh, Vienna, and Berlin, and received the degree of M D from his own university in 1878. For four years he was occupied with research on cancer for the Medical Department of the Local Government Board, and thereafter was demonstrator of anatomy at Cambridge for five years, taking the degree of M A (King's College) in 1880. He settled in London in 1881, and for the remainder of his life was largely occupied in the study of epidemiology and the preparation of books and numerous papers on subjects belonging to that department of science.

The death, in his 80th year, of Dr Charles Creighton should excite emotions of pride, shame, and sorrow in members of his profession, pride in his scholarly achievements, shame that his colleagues never paid him the tribute of respect willingly conceded to far smaller men, sorrow that what Johnson would have called the infirmities of his character, if they did not excuse, partly explained the cold hostility with which he was almost universally treated. Creighton was a voluminous writer, but it is practically certain that he will be remembered for two works. His translation of Hirsch's *Handbook of Historical and Geographical Pathology* for the New Sydenham Society secured him the kind of immortality gained by, say, Tieck and Sehlegel or North—namely, that earned by those who have made really available to foreigners the original text of an epoch-making work. His *History of Epidemics in Britain* admits him to the circle of great original writers, and is, in the strict sense of the word, a classic. The admirable literary style of this work can be appreciated by any educated reader, to assess its scholarship requires some independent experience of the subject matter. I have worked over a small part of the field and never detected any error of fact. But Creighton's historical scholarship was greater than is implied even by minute accuracy in citation and power of focusing the data. Anybody who studies the medical writers of the eighteenth and earlier centuries with a serious intention of understanding them eventually realizes that a great deal more is needed than mere study of the texts, that it is necessary to acquire a new sense of intellectual values by reading the books—particularly the Latin versions of the most popular works of Galen and Hippocrates—with the teaching of which the older epidemiologists were saturated. Although Creighton makes no parade of erudition it is obvious enough that he had taken these pains, and could, in the stock phrase of the *Arabian Nights*, both read a letter and understand it. He was wholly free from the neocentury error of supposing that because a writer of the seventeenth or eighteenth century uses words which, used as we use those words, seem nonsensical he was therefore writing nonsense. This was a great merit, a fine quality in an historical writer, but as Creighton had, like all other men, his share of human frailties, this very virtue betrayed him into a fault which his contemporaries had not generosity enough to forgive. The fault was that, while he tried to do justice to the past and succeeded in that aim, he never tried to do justice to the present. He despised the pseudo-historian who awards praise or blame in accordance with the extent to which the opinions or descriptions of the old writer can be

"identified" with those of modern idols of the market place. His reaction was either to ignore wholly or to mention with cold contempt those lines of thought and research which his own contemporaries highly prized. He acted in the spirit of the epigrammatist who said that whatever is generally believed is necessarily false. Contempt is more wounding to one's vanity than vehement attack. This habit of mind, together with the inevitable exploitation of his scholarship by one party to an acrimonious dispute, will explain the practical ostracism of Creighton. A very small number of Englishmen openly recognized him as the most learned epidemiologist we have ever produced, some others borrowed from him without acknowledgement or even affected a certain superiority, to most he was just Creighton the antivaccinator and—what more is there to be said?

Although Creighton will surely live as an epidemiologist, he seemed to value himself far more upon his microscopic work. I met him several times some twenty years ago in his friend Professor Bulloch's laboratory, and remember that he used to speak lightly of the amount of ability required for literary research in comparison with the demands made by work in the laboratory. But his literary conversation was fascinating. Those of us who gathered round Bulloch's tea-table will remember Creighton's brilliant solutions of literary puzzles. He had solved, or thought he had solved, most of the problems of literary identification. I recollect a particularly neat identification of the "four beasts full of eyes before and behind" of the Apocalypse: one stood for Isaiah, another for Jeremiah, another for Ezekiel, and the last for Daniel. Very likely—I am no judge—his pathology and his literary criticism may have been amateurish, but he was quite certainly something much bigger than a technical expert, he was a scholar and a gentleman.

It was rather hard to explain to Continental scholars who had a habit of assuming that Creighton was one of our great men, that the practical British mind could not take an antivaccinator seriously, they might actually suggest that such heterodoxies were of no more relevance to Creighton's work than Vichow's political alarms and excursions detracted from his scientific position! A dead man does not offend the herd instinct any more. Let us hope that now all will read the *History of Epidemics in Britain*.

M. GREENWOOD

#### ALEXANDER CAMPBELL, M.D., F.R.C.S., Dundee

We regret to record the death of Dr. Campbell, on July 10th, in his 86th year. He graduated at Aberdeen in 1865, settled in Dundee in 1870, and before long was appointed surgeon to the Royal Infirmary there. In the *Edinburgh Medical Journal* of July, 1874, he reported one of the earliest British cases of successful nephrectomy, a cystic tumour provisionally diagnosed ovarian being found to proceed from the lower pole of the kidney; the kidney and tumour were removed together. After ten years' service Dr. Campbell was appointed consulting surgeon, and he was several times a member of the board of directors. He was certifying factory surgeon and surgeon to the Post Office.

He was keenly interested in public affairs and served as surgeon-major of the Rifle Volunteers. In 1901 he was president of the Dundee Branch of the British Medical Association. He is survived by his elder son, Dr. A. Sydney Campbell, and by a married daughter, to whom we desire to express our sympathy.

### Medical Notes in Parliament.

[FROM OUR PARLIAMENTARY CORRESPONDENT.]

On July 29th, before Parliament adjourned for the Recess, the Royal Assent was given to the Diseases of Animals Act, Poor Law Act, Midwives and Maternity Homes (Scotland) Act and other statutes including the Finance Act and the Trade Disputes and Trade Unions Act. The House of Lords and House of Commons will both reassemble on November 8th. The Unemployment Insurance Bill will come before the Commons for second reading on November 9th. The Mental Deficiency Bill

and the Nursing Homes (Registration) Bill are awaiting consideration by the Commons on report, and both should be in law before Christmas.

### The Scottish Board of Health

#### Housing

On the Estimates for the Scottish Board of Health Mr. Adamson and other members discussed housing difficulties. Mr. James Stuart thought that the Government should accelerate the building programme in Scotland and compel local authorities to hasten. In Glasgow 277,000 people were living in overcrowded conditions according to the Scottish standard that three persons or more per room was overcrowding. The results were respiratory diseases, tuberculosis, measles and whooping-cough. Three children died of tuberculosis in the overcrowded areas of Glasgow for one in the well-to-do residential part. From measles the proportion of deaths was five to one and from whooping-cough seven to one. Even in the new houses 23 per cent of those who had come from the slums were living in overcrowded conditions. The number of houses required in Glasgow in 1919 was 57,000 to-day 107,000 were needed. In 1939 13,000 Glasgow houses were in a state to-day not fewer than 20,000. Dr. Elliot said the Scottish Board of Health was not responsible for policy. For the health of the country he said that the death rate from all forms of tuberculosis per 100,000 of the population in Scotland fell from 110 in 1925 to 99 in 1926 and the rate for deaths from non-pulmonary tuberculosis from 110 to 85. Compared with 1916 174 fewer people died in Scotland during 1926 from pulmonary tuberculosis and 1,071 from non-pulmonary tuberculosis. Reserved for treatment of tuberculosis were now 4,339 compared with 4,170 at the end of 1925. Infant mortality in 1925 was 23 per 1,000 or 8 less than the rate in 1925 and 13 less than that for the preceding ten years. It was the lowest rate on record except that for 1923, despite last year's unemployment and depression in the coal trade. He agreed there was a high death rate in the crowded areas but that could not be attributed only to one factor. It was also correlated to the low rate of unemployment in Dundee, an overcrowded city infantile mortality was lower than in Aberdeen. Mr. Stewart intervening said that in the Rose Street district of Glasgow the infantile death rate was 235 per 1,000 children born against an average for the city of 107 and that the rate for the congested districts remained practically steady. Dr. Elliot said that this year to the beginning of July houses had been built to meet the whole of the year's housing requirements for Scotland—practically 10,000 houses. He hoped another 6,000 would be built before the end of the year.

#### Highlands and Islands Medical Service

Mr. Macpherson referred to the Highlands and Islands Medical Service Fund drawing attention to the fact that it was still at the pre-war figure of £12,000. The Highland doctor did splendid work often for a miserable fee. He asked whether the attention of the Secretary for Scotland had been drawn to the appeal by the medical officers for the establishment of a superannuation fund. The local doctor in remote parts should be guaranteed a house or the site of a house. Last year the Board of Health had caused three houses to be built for doctors. That was well worth doing.

Dr. Elliot said the Highlands and Islands Fund had an accumulated balance out of which the Board of Health was drawing between £18,000 and £20,000 a year. By 1923 or 1929 that balance would be exhausted and the Secretary for Scotland would ask the Treasury for an increase in the sum given for medical benefits to the Highlands and Islands. An occasion for this approach would be found in the reconstitution of the fund which had been recommended. The vote for the Board of Health was carried.

#### Scottish Prisons

On a subsequent vote for Scottish prisons, some protests were made about the sending of persons to prison for minor offences. Sir John Gilmour in reply said that Scotland admitted a larger behind England in the use of probation but the Scottish Office was investigating the problem and he hoped progress would be made. Prison administration particularly at the new prison in Edinburgh was an advance on anything previously seen. This vote was also carried.

#### Public Education in Scotland

On the vote for public education in Scotland Mr. Maxton remarked that Glasgow had to be responsible for two-thirds of the physically defective and two-thirds of the mentally defective children in all Scotland; this he argued showed that a high percentage of Glasgow children were in a condition which tended to make them defectives. The debate was adjourned.

#### Irish

Answering Mr. Forrester, Mr. Chamberlain said that it was a curative agent in the ordinary sense. No anti-cancer treatment was possible at the number of persons who had received it. It was not possible to ascertain in how many cases it had been of use in the treatment of ulcers had contributed to the cure of cancer.

Projects of Irish emigration.—Mr. Neville Chamberlain states that as soon as consideration of the committee's report on the recent Royal Commission on National Health Insurance has been completed the Government hopes to introduce legislation and the question of the compulsory insurance of fishermen both in England and Scotland is so far as it is not already included in the scheme would be dealt with in legislation.

#### Election of Officers

The following officers were elected—*Generals* Sir Edward  
Farquhar Bazzard K C V O M D Frederick John Poynton  
M D John Walter Carr C B E M D Arthur Philip Beddard  
M D Emeritus *Treasurer* Sir Dyce Duckworth Bt M D  
*Treasurer* Sidney Philip Phillips, M D *Registrar* Raymond  
Crawford M D *Harveian Librarian* T H Arnold Chaplin M D  
*Assistant Registrar* Robert Oswald Moon M D

Sir Hugh Kerr Anderson was elected a Councillor in the place of  
Dr J H. Sequeira resigned

#### Harveian Orator and Lecturers

The President announced that he had appointed Sir Humphry  
Rolleston to deliver the Harveian Oration in 1928 and the Registrar  
reported the following acceptances of appointments: Dr G J Still  
as FitzPatrick Lecturer for 1928 Dr J S Collier as Linnæan  
Lecturer for 1928 Dr E P Boulton as Oliver Sharpey Lecturer for  
1928 Dr H H Dale as Croonian Lecturer for 1929 Dr T Izod  
Beunett as Goulstonian Lecturer for 1928

#### Moxon and Baly Medals

On the recommendation of the Council the Moxon medal was  
awarded to Sir Henry Head M D F R S, and the Baly medal to  
Professor A V Hill F R S

#### Marchmont Scholarship

The award by the University of Edinburgh, of the Marchmont  
Scholarship to Mr John M Michael, an undergraduate of that  
University, was announced

#### Various Communications

Communications were received from the secretary of the Royal  
College of Surgeons reporting the proceedings of the Council of  
that College from the Board of Trade asking the College to advise  
them whether a suitable microscope should be part of the com-  
pulsory medical instrument equipment of ships that are required  
to carry a medical officer from the secretary of King Edward's  
Hospital Fund for London asking if the College would desire to  
give evidence before the special committee of inquiry called the  
Pay Beds Committee Dr C McMoran Wilson and Dr J H  
Thursfield were nominated

#### The Secretary of the Conjoint Examining Board

A report was received from the Committee of Management of the  
Examining Board in England stating that it had received a com-  
munication from Mr F G Hallett expressing his desire to retire  
in December next from the post of secretary of the Examining  
Board in England Mr Hallett was appointed the first secre-  
tary of the Board in January 1886 but had joined the office  
staff of the Royal College of Surgeons in December 1877 and had  
become assistant secretary to the College in 1882 he had therefore  
completed fifty years of service at the Royal College of Surgeons  
and the Conjoint Board On the motion of Sir William Hale  
White it was resolved unanimously that an expression of much  
regret at his resignation and of the great appreciation felt by the  
College for the ability zeal and devotion with which he had  
carried out his duties for nearly fifty years should be conveyed to  
Mr Hallett The recommendation of the Committee of Manage-  
ment that Mr Horace Hayter Rew who has held the post of  
assistant secretary to the Examining Board for the last seven  
years should be appointed secretary as from December 5th was  
accepted

#### Recognition of Universities and Colleges

The following institutions and colleges were added to the list of  
institutions whose graduates in medicine are admissible to the  
final examinations in medicine surgery and midwifery under  
the conditions of Paragraph IV Section III of the old Regulations  
and Paragraph III, Chapter III of the Regulations dated January  
1st 1923—namely The Masaryk University of Brno Czechoslovakia  
the Kornensky University of Bratislava Czechoslovakia  
the Medical College of Virginia Richmond U S A, the Meharry  
Medical College Nashville Tennessee U S A

#### ROYAL COLLEGE OF SURGEONS OF ENGLAND

An ordinary Council meeting was held on July 23th when the  
President Sir Berkeley Moynihan Bt was in the chair  
Mr W Thwaites Thomas was admitted to the Council

#### Diplomas and Licences

Diplomas of membership were granted to 172 candidates The  
Licence in Dental Surgery was granted to Lilian Mary Jocelyne  
Diplomas were granted jointly with the Royal College of  
Physicians in public health to 27 candidates in ophthalmic  
medicine and surgery to 19 candidates

#### Board of Examiners

Mr J Lewin Payne was re-elected a member of the Board of  
Examiners in Dental Surgery

#### Lister's Surgical Notes

The College accepted the custody of Lord Lister's Surgical  
Notes which had been offered to the College for permanent loan  
by the Committee of Management of King's College Hospital, upon  
the recommendation of the medical board

## Medical News.

APPLICATIONS for the Milroy Lectureship for 1929 are  
invited by the Royal College of Physicians of London  
The lectures must be on some subject in State medicine and  
public health, and copies of Dr Milroy's suggestions and  
further information can be obtained from Dr Raymond  
Crawford, Registrar Royal College of Physicians of London,  
Pall Mall East, S W 1 It should be noted that applications  
must be received by the Registrar on or before September  
28th, which is earlier than has been usual Further par-  
ticulars will be found in our advertisement columns

THE general secretary Dr Hugh Woods, of the London  
and Counties Medical Protection Society has called our  
attention to a letter he has addressed, on behalf of the  
society, to the town council of Ramsgate It appears that  
some time ago charges were made against the police surgeon  
Dr A J K Drew, with regard to the manner in which he  
gave evidence in an inquiry relative to a member of the  
Famsgate police force It is stated that Dr Drew has not  
obtained a formal statement of the charges, and that the  
only information he had as to their nature was given to him  
at an informal meeting of the Watch Committee Dr Drew  
communicated with the society of which he is a member  
but its solicitors have been unable to obtain particulars of  
the charges and complaints, and the *Thanet Advertiser* on  
July 2nd announced that the town council had unanimously  
resolved in committee to give Dr Drew three months notice  
to terminate his appointment as police surgeon The secretary  
of the London and Counties Medical Protection Society in his  
letter to the town council, observes that its action, in view of  
the publicity of the circumstances is virtual dismissal The  
object of the society's letter appears to be to extract from  
the town council a statement formulating the charges against  
Dr Drew, so that he may have an opportunity of an un-  
prejudiced hearing and of a decision given after full investi-  
gation

PROFESSOR ROBERT HOWDEN has resigned the chair of  
anatomy in the College of Medicine Newcastle upon Tyne  
(University of Durham), which he has held for thirty eight  
years, he has been elected emeritus professor Professor  
Howden is well known to medical students as the editor of  
Gray's *Anatomy*, the last edition of which (the twenty third)  
was reviewed in our columns last December Professor  
Howden has been the representative of the University of  
Durham on the General Medical Council since 1918

At the annual meeting of the British Spas Federation  
which was held at Strathpeffer a small committee was  
appointed to develop further research into the chemical and  
physical properties of the mineral waters of Great Britain  
It was decided to take steps to draw attention to the import-  
ance of the fullest use of British spas both from the stand-  
point of national health and as a means of restoring the  
adverse balance due to the large English expenditure at  
foreign resorts

MR CHAMBERLAIN Minister of Health has during the  
temporary absence of Captain Bras M P who is accom-  
panying Mr Amery on his tour of the Dominions appointed  
Mr Geoffrey Peto, M P, to be his Parliamentary Private  
Secretary

THE fifth gold medal of the African Society instituted for  
presentation to those who have done the best work for Africa,  
has been awarded to Sir Ronald Ross K C B, F R S, F P S

At the annual meeting of the Automobile Association it  
was stated that in little over twenty years it had obtained  
a membership of nearly 350 000 that it disposed of an income  
which was not far short of £700 000 and that its services to  
its members facilitated travel not only in this country but  
practically throughout Europe Improved arrangements had  
been made with Austria, Germany, Norway, Spain and the  
Irish Free State The association can induce to press for  
reintroduction of the petrol tax In this connection it has  
been suggested that the horse power tax handicaps the  
British manufacturer in foreign trade by preventing the pro-  
duction of cheap high powered six cylinder engines such  
as are suitable for very hilly country

THE fifth International Congress for the Protection of  
Childhood held at Madrid in April 1925 decided that the  
next congress should be held in Paris in 1928

THE fifth French Congress of Stomatology will be held in Paris, under the presidency of M. Gires, from October 24th to 30th, when the following papers will be read: surgical extraction of teeth, by M. Monier, osteitis of the lower jaw, by M. Gornovec. The following subjects will also be discussed: buccal hygiene of children at school and at home, introduced by M. Teller, sterilization in stomatology, introduced by M. Fargin-Fayolle. Further information can be obtained from the general secretary, M. Lecleercq, 9, Boulevard de la Madeleine, Paris, 1<sup>re</sup>.

THE celebration of the fiftieth anniversary of the French Society of Public Health and the fourteenth Congress of Hygiene will be held at Paris from October 25th to 28th at the Pasteur Institute, with Dr. Roux, director of the institute, as president of honour, and Dr. Léon Bernard, professor of hygiene in the Paris Medical Faculty, as president. Papers will be read by Professor Madsen of Copenhagen on the international organization of public health, and by Professor Dopfer, of the Val de Grâce Military Hospital, on military hygiene. Further information can be obtained from the secretary, Dr. Dujarric de la Rivière, 26, Rue Dutot, Paris, XVI<sup>e</sup>.

## Letters, Notes, and Answers.

All communications in regard to editorial business should be addressed to **The EDITOR, British Medical Journal, British Medical Association House, Tavistock Square, W C 1**

ORIGINAL ARTICLES and LETTERS forwarded for publication are understood to be offered to the **British Medical Journal** alone unless the contrary be stated. Correspondents who wish notice to be taken of their communications should authenticate them with their names not necessarily for publication.

Authors desiring REPRINTS of their articles published in the **British Medical Journal** must communicate with the Financial Secretary and Business Manager, British Medical Association House, Tavistock Square, W C 1 on receipt of proofs.

All communications with reference to ADVERTISEMENTS, as well as orders for copies of the **JOURNAL**, should be addressed to the Financial Secretary and Business Manager.

The **TELEPHONE NUMBERS** of the British Medical Association and the **British Medical Journal** are **MUSEUM 9361, 9362, 9363**, and 9364 (internal exchange, four lines).

The **TELEGRAPHIC ADDRESSES** are

LD110R of the **BRITISH MEDICAL JOURNAL, Aitiology Westcent, London**

FINANCIAL SECRETARY AND BUSINESS MANAGER  
(Advertisements, etc.), **Aitcliffe Westcent London**

MEDICAL SECRETARY **Mediscera Westcent, London**

The address of the Irish Office of the British Medical Association is 16, South Frederick Street, Dublin (telegrams **Bacillus, Dublin**, telephone 4737 Dublin), and of the Scottish Office, 6, Drumsheugh Gardens, Edinburgh (telegrams **Associate, Edinburgh**, telephone 4361 Central).

## QUERIES AND ANSWERS

### RAISING A BOOT FOR SHORT LEG

DR W. D. HOPKINS (Hayes, Middlesex) writes: When a boot is to be raised an inch or so I have usually had it done with an extra leather sole, which makes a weighty article for feeble muscles. What inexpensive method can be used to add the least weight?

\* \* We have referred this question to Mr. E. Muirhead Little, who has been good enough to reply as follows:

When a boot or shoe is to be raised an inch at the heel and not at the tread a piece of cork of that thickness can be fitted inside the shoe, and in such a case it is not always necessary to alter the leatherwork of the shoe. A leather heel of, say, 2 in. (in place of the usual 1 in.) is not heavy enough to matter much, but above that height the weight is important, and cork is preferable. Two inches or even more may be placed inside the boot, but, of course, in that case the boot must be specially made to take it. Larger amounts are placed in whole or part outside the boot between the welt and the sole. For the sake of appearances part of the cork may be placed outside and part inside the boot. It is only possible to adapt an ordinary boot when the amount of shortening to be accommodated is small, say up to 1½ in. at most. For greater disparity specially made surgical boots are needed. There seems to be no inexpensive method of raising the height of the heel and sole beyond a small

amount, but any bootmaker should be able to insert 1/2 in. of cork between sole and welt without difficulty, although he will generally decline the job as being "surgical."

### INCOME TAX

#### Three Years' Average

"J. V. B." claimed, and was allowed as for an expense of the year 1925, £310 as the cost of replacing his car. For 1927-28 he will be assessed on the basis of the 1926 earnings, and therefore will lose two thirds of the benefit of the renewal allowance. Has he any remedy?

\* \* The cost of renewal has to be treated in the same way as any other professional expense, and no special claims can be made to set a portion of it against the 1926 profits. If, however, "J. V. B.'s" profits for 1925, as adjusted for income tax purposes, were less than the average earnings of the practice for the six years up to and including 1923—or for such shorter period as he may have been the owner of the practice—he can claim to be assessed for 1927-28 and 1928-29 on the basis of the three years' average, in accordance with Section 29 of the Finance Act, 1926-27. His claim must be lodged by October 5th.

## LETTERS, NOTES, ETC.

### THE "MEDICAL DIRECTORY"

THE Editors of the *Medical Directory* inform us that their annual circular has been posted to each member of the medical profession. Should any form not have reached its destination, they will be glad to send a duplicate. They hope that complete forms may be sent to them at 7, Great Marlborough Street, London, W., by an early post.

### MEDICAL MARKSMEN

DR C. W. WIRGMAN (London, E.C.) writes: I was glad to see the excellent notice given in the *JOURNAL* of July 23rd to the victory of Dr. C. H. Vernon at Bisley. It is curious that the medical profession have in the last three years twice occupied the second place and won this year. A very strong team of ten could have been got up from among doctors attending the meeting. The following attended and had a very good meeting on the whole: Captain A. B. Bratton, D.S.O., M.C., Colonel H. D. Brook, V.D., J. Elgood, M.J. Barker, Colonel L. Langford Lloyd, D.S.O., F. H. Kelly, Colonel W. F. McLean, G. Robertson, G. C. I. Robinson, Captain C. H. Vernon, Major C. W. Wirgman.

\* \* We take this opportunity to correct an error in our note on the King's Prize-man. Dr. Vernon's age is 35, not 45.

### TREATMENT OF VARICOSE VEINS BY INJECTION

MAJOR GENERAL T. M. CORRIE, A.M.S., draws attention to recent references in our columns to the treatment of varicose veins by injection (February 26th, p. 375, and *Epitome*, March 12th, para. 286) and suggests that some clear statement is desirable as regards the possible danger of thrombosis. He adds that if there is little risk of trouble from this cause, the advantages of the injection treatment, particularly the avoidance of a cutting operation, and the rapidity with which recovery seems to follow, would render this procedure worthy of more thorough investigation, with a view to its general adoption. He invites comment from those who have had experience of the results of treating varicose veins in this way.

### PORTUGAL FOR THE TOURIST

WE have received an illustrated pamphlet about Portugal, published by the Sociedade Propaganda, and extolling the beauties of that country in climate, landscape, and watering places. The pamphlet was published in 1916, it has only just reached us, presumably, because, as the preface states, "the functioning of the various services" during the war was "somewhat less regular." It is noted that the political and geographical situation of Portugal in face of the European conflagration, readily explained the influx of foreigners, who were quietly awaiting an opportunity to return to their own lands. The pamphlet might have mentioned also that the national industry, revolution, is carried on in a gentlemanly manner, with a minimum of bloodshed. We fully agree that the country is admirably adapted for the development of "tourism," and the well known affection of the Portuguese for the English makes it additionally attractive. The illustrations of scenery and buildings in the pamphlet invite the visitor. The address of the Sociedade Propaganda de Portugal in 1916 was Rua Garrett, 103, Lisbon.

### VACANCIES

NOTIFICATIONS of offices vacant in universities, medical colleges, and of vacant resident and other appointments at hospitals, will be found at pages 31, 32, 33, 36 and 37 of our advertisement columns and advertisements as to partnerships, assistantships, and locum tenencies at pages 34 and 35.

A short summary of vacant posts notified in the advertisement column appears in the *Supplement* at page 100.

## THE RELATION OF PREGNANCY TO GENERAL DISEASES

### I—CARDIAC DISTURBANCE

BY

J. M. MUNTO KEPR, M.D.

Peggy Professor of Midwifery, Glasgow University

THE choice of the Committee in selecting cardiac diseases in relation to pregnancy as one of the subjects for discussion in the Section of Obstetrics and Gynaecology is particularly appropriate, for in Scotland at least it will always be associated with the name of Angus Macdonald whose early death was such a loss to the Edinburgh school of obstetrics.

Much has happened since Angus Macdonald's monograph appeared in 1878. Cardiology to-day is an infinitely more complex subject. The mechanical methods of diagnosis have been enormously developed. But with all the modern and more exact methods of diagnosis, the real test the "acid test" of the journalists, still remains—the response of the heart makes to the call of increased work, and if organically diseased and disturbed in function the response it makes to such simple methods of treatment as rest, suitable diet, and improved elimination.

In approaching the subject of cardiac disease in pregnancy, the first question which naturally arises is the effect pregnancy has upon the anatomy and physiology of the healthy heart. Considering the large number of investigators who have interested themselves in cardiology one would have thought that by this time definite decisions would have been reached. But this is not so. Take the simple question of hypertrophy of the left ventricle during pregnancy: does it, or does it not, occur? Is there a work hypertrophy, or is the extra effort brought about by its latent reserve? Sir Thomas Oliver, writing the other day, states, "On the whole the consensus of medical opinion is that in pregnancy there is a slight increase in the size and weight of the heart, and my own experience confirms this." Sir James Mackenzie held the other view. Here are his words: "The assumption that the heart hypertrophies during pregnancy is not justified. All this additional work is met by a call upon the reserve force." The latest contribution to the subject which has come to my notice is by Jensen and Norgaard; it is entitled "Studies of the functional cardiac diseases and the essential cardiac hypertrophy in normal pregnancy," and is based upon observations in 239 cases of pregnancy. These authors state "The roentgenograms showed an increase in 60 per cent of the pregnant while the electrocardiograms showed hypertrophy in all the cases examined. This means that a cardiac hypertrophy is of normal occurrence during pregnancy and that it is associated with dilatation of the heart in about 60 per cent of the cases."

Percussion gives little information except in gross cardiac enlargement for during the later weeks of pregnancy the heart in health is displaced upwards and backwards, the apex beat being often felt in the fourth interspace with the left margin of dullness displaced outwards.

As regards the physiology, again we find differences of opinion even on such a simple question as blood pressure. This undoubtedly is due in some instances to the fact that in pregnancy variations in blood pressure readily occur from disturbances in metabolism, the toxæmia of pregnancy, etc. In normal pregnancy there is no increase in blood pressure. Next to the systematic examination of the urine, estimation of the blood pressure is probably the most important detail in the medical examination of the pregnant woman. We are all familiar with the danger signal of a distinct rise in blood pressure associated with the toxæmias, a distinct fall in blood pressure is also a danger signal.

Report on a discussion in the Section of Obstetrics and Gynaecology at the Annual Meeting of the British Medical Association in Edinburgh (Wednesday July 26th). Dr James Haig Ferguson, President of the Section was in the chair.

The pulse rate is very easily disturbed in the later weeks of pregnancy. Slight exertion often produces a marked increase in the rate, which falls relatively soon on resting. I have observed marked tachycardia in quite a number of cases, and in two with very pronounced enlargement of the thyroid gland. Paroxysmal tachycardia is occasionally encountered, and for it is not necessarily serious.

Lastly, there is the increase in the body weight, blood volume, and cardiac output—all playing a part in effecting variations in normal activity.

The functional disturbances which may occur are palpitation, tachycardia, slight cardiac irregularities, dyspnoea on exertion, soft blowing murmurs over the pulmonary area, and accentuation of the second sound. Some are undoubtedly mechanical, from pressure of the enlarging uterus; others of a much more subtle origin, are caused by disturbed innervation, alterations in metabolism and over activity in the endocrine glands, more especially the thyroid.

Putting aside the cases in which there is no great difficulty in deciding that the disturbance is purely functional and not organic we come to those of a definitely organic nature—the lesions associated with murmurs and irregularities of cardiac force and rhythm. Here we find a unanimity of opinion that in the condition of the heart muscle which determines the seriousness of the lesion. Thus the cardiologists have concluded that in dealing with pregnant women the problem is complicated by the fact that pregnancy is associated in many instances with insidious metabolic disturbances and overactivity in the ductless glands, disturbances which in themselves may play an important part in aggravating a tendency to decompensation.

Within the last year several important contributions to our subject have been made by physicians and obstetricians. There are the remarks made by Price at the Annual Meeting last year, the interesting lecture by Sir Thomas Oliver, the discussion on heart disease and pregnancy at the February meeting of the Midland Obstetrical and Gynaecological Society, and lastly an important contribution by Fennie, made to the Sixth British Congress of Obstetrics and Gynaecology in Manchester in April of this year. Reading the remarks of the different contributors who introduced or took part in the discussions one finds a general consensus of opinion on such questions as: (1) the gravity of the condition, (2) the distress signals manifested, and (3) the treatment to be employed. This highly satisfactory result has been reached by co-operation between physicians and obstetricians and is a testimony to the value of co-operation in the consideration of problems that affect the domain of both these branches of medicine. Every maternity hospital should have its visiting physician. There is in the ante-natal wards of all maternity hospitals invaluable material for medical research.

Let me discuss the question under the headings just mentioned.

#### 1. THE GRAVITY OF THE CONDITION

Our experience in the Royal Maternity Hospital in Glasgow is that cardiac disease takes a heavy toll of its victims. In Lenné's series of 2,400 there were 19 deaths—that is, a mortality of 22 per cent. Other writers of the subject have recorded a lower and many a higher, mortality rate. The figure is probably somewhere between 15 and 25 per cent. I give here a summary of the cardiac cases in all admitted to the Glasgow Maternity Hospital during 1926. The records have been kept with particular care and supervised by Dr Cruickshank.

(Cardiac Cases, 1926)

During the year 1926 the cardiac cases admitted to the hospital numbered 53 (approximately 16 per cent of all admissions). Of these patients 7 died in the ward and 51 were dismissed alive. 47 were delivered and 11 were undelivered. 39 of the patients were under ante-natal supervision. 16 were sent in as emergency cases and 3 applied for admission at the onset of labour. 5 of the fatal cases had been under ante-natal treatment and the remaining 2 were emergencies.

*Mode of Delivery*

As stated previously, 47 of the 58 cardiac cases were delivered, and the mode of delivery was as follows:

Spontaneous delivery (including spontaneous abortion)	30
Forceps delivery	6
Induction (including two abortions)	4
Cæsarean section	6
Hysterectomy	1
	47

*Spontaneous Delivery*—In 30 cases there was spontaneous delivery, with 3 maternal deaths, 1 abortion, 1 stillbirth, and 28 live born children (29 including twins), 1 premature child died.

*Forceps Delivery*—In the 6 cases of forceps delivery there were no maternal deaths and no stillbirths, but 1 premature child died some days after delivery.

*Induction*—All 4 cases of induction were under ante natal treatment. One was an induced abortion and 3 were induced near term, 3 living, though premature, infants were obtained.

*Cæsarean Section*—All 6 mothers delivered by Cæsarean section recovered. One had been sent in as an emergency, and the others were treated in the ante natal wards, 4 living, and 2 stillborn, children were delivered.

*Hysterectomy*—The 1 case of hysterectomy (at the third month) resulted in the recovery of the mother.

*Fatal Cases*

Seven of the 58 cardiac cases resulted in the death of the mother. The youngest of these 7 patients was 27, the eldest was 44, and the mean age was 32.3 years. The parity of the fatal cases ranged from 3 to 9, with a mean of 4.6 pregnancies. All the fatal cases were examples of mitral disease, and 2 had definite auricular fibrillation. There were two examples of ulcerative endocarditis. The mode of delivery in the fatal cases was as follows:

<i>Mode of Delivery in 7 Fatal Cases</i>	
Spontaneous	2
Forceps	Nil
Induction	2
Cæsarean section	Nil
Hysterectomy	Nil
Not delivered	3

## 2 EVIDENCES OF APPROACHING DANGER

In many cases, although there is an improvement in this direction in recent years, decompensation had reached an advanced stage at the time of admission. It is very desirable that cardiac cases should be sent into hospital early, so that ordinary medical remedies may have a fair trial.

In patients with failing compensation who improved in the early months and were allowed to leave hospital prior to delivery, recurrence of decompensation was much more difficult to correct, and in some cases was impossible on the subsequent admission.

Undoubtedly all evidence in favour of a general tendency to earlier and more pronounced decompensation with each succeeding pregnancy. Specially anxious must one be if, prior to the pregnancy, there is a history of unsatisfactory compensation, or a compensation readily unbalanced by slight exertion or any mild intercurrent ailment.

As already mentioned the condition of the myocardium calls for first consideration. In judging of this the opinion of a physician is of inestimable value to the obstetrician. Mackenzie states that "evidences of heart failure are to be found not in the examination of the organ but in the manner in which the circulation is maintained in the different organs of the body." Thus dusky skin of the face, slight increase in the respirations, occasional crepitation at the bases of the lungs, and breathlessness on slight exertion, are often more important indications than occasional cardiac irregularity that a heart is beginning to find the strain too great. Generally speaking, at this stage, with careful nursing, dieting, etc., the pregnancy, labour, and puerperium can be safely negotiated. Less certain is the outlook and prognosis when cyanosis, oedema, and albuminuria are present, and when crepitation is continuous. We get a considerable number of cases sent into the wards at this stage, and it has always been my practice in such cases, no matter what the nature of the cardiac lesion, to try for a week or ten days the effect of the recognized treatment for cardiac decompensation. If no improvement results the pregnancy is terminated. Patients the subjects

of cardiac disease improve very soon, if they are going to improve, so that a week or ten days is almost always sufficient.

When the decompensation is more pronounced, the heart is enlarged, and other organs are markedly disturbed as a result of a weakening myocardium, the sooner the pregnancy is terminated the better.

Only a word or two is necessary regarding the various valvular lesions from one whose knowledge of cardiology is limited.

*Aortic Regurgitation*—I have seen comparatively few examples of this lesion. Relatively speaking, they are not very common in pregnant women. Lennie's figures for the Glasgow Maternity Hospital show its occurrence in 4.7 per cent. All writers are agreed that decompensation in this condition is very serious. Especially grave is a much enlarged heart with a "Corrigan" pulse. With good compensation I have seen several women pass through pregnancy and labour with comparatively little disturbance. But even in the absence of marked decompensation I should be inclined to terminate pregnancy if moderate effort produced distress. For with aortic regurgitation, once distinct decompensation develops it is generally impossible to arrest the progress downhill. The immediate prognosis and the treatment are comparatively simple, therefore, with this particular lesion, and operative treatment should not be too long delayed.

*Mitral Regurgitation*—I have had many cases of mitral regurgitation under my care. My personal experience is that if the condition of the cardiac muscle is satisfactory the prognosis is good both as regards the pregnancy and the labour. This is borne out by Lennie's figures—one death in 17 cases (7.8 per cent.) of simple mitral regurgitation contrasting with a fatality of 24.5 per cent for mitral stenosis. It is seldom difficult, therefore, to decide when a patient with simple mitral regurgitation may be safely left to continue in her pregnancy.

*Mitral Stenosis*—This lesion has always seemed to me the most difficult to gauge, as a clinical study it is much the most interesting of all the cardiac murmurs. Of the grave examples of cardiac disease complicating pregnancy it is the one which most frequently gives us concern during pregnancy and labour. My own personal experience of this lesion has led me to view with grave concern any example of the condition when there are marked cardiac irregularity, crepitation at the bases of the lungs, breathlessness on the least exertion, and especially if these symptoms were not relieved by simple treatment. The danger signals have been wonderfully described by a great master. Chapter IX of *Heart Disease in Pregnancy* is most fascinating reading. The story of how, as the disease progresses, the murmur changes in character, auricular fibrillations and other features appear, seems to me a perfect example of exact clinical observation. Very interesting too, are the remarks of Price at last year's meeting of this Section.

## 3 TREATMENT

I now turn to the treatment of this condition, and more particularly to the obstetric treatment, for this is a subject regarding which there are differences of opinion amongst obstetricians and rather vague views are held by many physicians. While in a considerable number of instances a damaged heart stands up to the strain of pregnancy to a surprising degree and no obstetric intervention except shortening the second stage by forceps delivery is necessary, there are undoubtedly many exceptions. The mistake, therefore, may be made of delaying obstetric treatment too long, just as there may be the mistake in initiating it too soon. Here I would again emphasize the importance of co-operation between physician and obstetrician. It is quite unnecessary to describe in detail the management of a cardiac case in pregnancy when the cardiac condition justifies one in adopting an attitude of watchfulness and employing ordinary medical remedies. I feel my contribution to the discussion will be most useful if I refer to my own clinical experiences in the grave examples of cardiac disease. I will presume that the physician and obstetrician have consulted, ordinary medical treatment has been employed and proved inadequate, and it is decided that

the symptoms indicate that the pregnancy should be terminated. How is it to be done?

At the outset permit me to state that operative intervention—that is to say, the artificial termination of pregnancy—is not infrequently the immediate cause of the patient's death (1) because it is too long lived (2) because the most suitable method is not employed. The first of these causes I have already mentioned, and the fatalities due to it, although not so numerous to-day as formerly, are not inconsiderable. No obstetricians still encounter in our private and hospital work too many examples of cardiac disease in pregnant women where the question of terminating the pregnancy should have been considered much earlier. As regards the second cause—the method of terminating the pregnancy—I find that many consulting physicians and general practitioners are not fully alive to the importance of selecting the method which will cause the patient the least amount of shock. Many consulting physicians and general practitioners think that emptying the uterus is a simple procedure, but this is not the case. In the early months induction of abortion necessitates dilating the cervix prior to removal of the ovum. All are familiar with the fact that stretching or dilating a sphincter has a very pronounced depressive effect on the heart, especially if it is done rapidly. If to avoid this one employs the more gradual method in tents—a common procedure ten or fifteen years ago—time is lost. Further, although one can introduce laminaria tents without an anaesthetic in a multipara it is difficult to do this in a primipara and at the same time take every precaution against septic infection. I have long been convinced therefore that where the uterus has to be emptied in the early months vaginal hysterotomy (vaginal Caesarean section) should be employed. It is a comparatively simple operation can be performed in ten or fifteen minutes, at one "sitting," and is attended with little shock.

In terminating a pregnancy in the later weeks the ordinary procedure is to induce labour by bougie. This in a multipara is not difficult, and can often be done without anaesthetizing the patient, but in a primipara it is much harder, because the cervix is closed and must be dilated to a slight extent, unless one is going to employ the simplest of all methods—rupture of the membranes. Besides, prior to carrying out these manipulations, it is very important that the canal should be disinfected, and this is not easy in a primipara unless she is anaesthetized. But there is another and even greater objection to induction of labour—namely, that there is no guarantee that one or two days may not elapse before labour starts. Thus the patient, already in a critical condition, is, if the ordinary method is employed, faced with the disturbance from the anaesthesia, the nervous tension of waiting for the labour to start, and, finally, the strain of the labour. It is not surprising, therefore, that the results from this method of treatment are, generally speaking, unsatisfactory. In Lennie's group of cases this method shows a mortality of 44 per cent, whilst in Cruikshank's table for last year the mortality was 50 per cent. Similar unsatisfactory results have led many of us to advocate Caesarean section, and it gives me special pleasure to tell you that Lennie's figures for Caesarean section in 17 cases show a mortality of 11 per cent, while last year, in the 6 cases in which this operation was performed, there were no deaths. As further evidence of the wisdom of selecting this operation I would remark that some of the worst cases admitted to the hospital were treated by this purely surgical procedure. I feel convinced we shall see in the future Caesarean section the accepted treatment for grave cardiac conditions where pregnancy has to be terminated in the later months. There is one peculiar advantage of abdominal Caesarean section for this condition—it permits the operator to sterilize the patient by excising a portion of the Fallopian tubes. He may even perform hysterectomy and conserve the ovaries if he deems this advisable. Undoubtedly there is something to be said for bringing about a cessation of the menstrual discharge while conserving the ovaries in function.

As regards cases in which labour comes on spontaneously, in many of them the termination is satisfactory if ther are 1) it alone, or if the second stage is shortened by forceps

In the cases for last year spontaneous delivery took place in 30 cases with 2 deaths (6 per cent) and forceps delivery was employed in 6 cases with no deaths. But I feel convinced that in a number of the gravest examples of cardiac disease it is a wiser procedure to employ Caesarean section. Particularly does this apply to primiparae, for delivery of a primipara with forceps in order to shorten the second stage produces distinct shock. The child has to be dragged through the vagina not previously dilated.

As you will see from the above record of cases, forcible dilatation of the cervix, manually or by instruments, was not employed. I know few conditions for which accouchement force is suitable, and certainly cardiac disease is not one of them. The unsatisfactory results from accouchement force are illustrated in Lennie's series, where this method of treatment shows a mortality of 50 per cent.

It is generally believed in this country that the parturient runs little if any danger from chloroform, and this has been my experience. But it would be folly to maintain, as some have done, that chloroform is the ideal anaesthetic for patients suffering from cardiac disease. I would like to have the views of expert anaesthetists on this subject. The more I operate the more importance do I attach to the administration of the anaesthetic. I am convinced that the anaesthesia induced by the "finished artist" not only materially lessens the ordinary discomforts following operation, but very decidedly affects the mortality and morbidity.

I cannot conclude this paper without referring to the fatalities in the puerperium. Anyone who has had to deal with a large number of cases of cardiac disease complicating pregnancy must have experienced the disappointment of fatalities occurring three or four days after labour. The pregnant and labour are satisfactorily tided over, all seems well after the delivery and on the day following, and even on the second and third day, and then failing compensation sets in and nothing can be done to save the patient. Angus Macdonald<sup>1</sup> refers to this, and every obstetric clinician is aware of it. What is the explanation? I have often spoken to my students about it and I have now and again been able to let them see the disaster occurring. Two special factors probably play a part in this particular type of decompensation: (a) a degeneration of the hypertrophied muscle fibres, and (b) absorption from the decidua debris in the uterus. Further, at the post-mortem examination in a number of cases there are distinct evidences of an acute endocarditis superimposed on the chronic valve lesion. Cruikshank refers to two examples of this in the summary of the cases already given.

The patient suffering from cardiac disease must receive, therefore, in the puerperium very particular care and attention.

## II—TUBERCULOSIS

BY

E. PISTON D. P. PARIS

It is a curious fact that the very unfavourable influence exerted upon lung tuberculosis by pregnancy should have been completely overlooked in the past, and that at the present day there should still be a small proportion of physicians who doubt it or even deny it. Hippocrates believed that pregnancy was the best cure for consumption, and his to us very surprising opinion was followed blindly along the twenty centuries during which medicine was hardly anything else than a dogmatic systematization of the Hippocratic creed. We, of course know better now, and the serious aspect of the coincidence of pregnancy with tuberculosis has become a matter for study and research. There is no same physician, I am sure, who would not strongly object nowadays to a tuberculous girl being married. But there are perhaps still some who would

object more on account of the menace to the progeny than of the danger to the expectant mother. And we still hear occasionally of medical men who, while admitting that there is such a danger, nevertheless believe that it has been, to a certain extent, exaggerated, and that a noteworthy proportion of consumptive women are able to bear children without having to pay a heavy tax for it.

I have been interested in that problem for many years, and after having carefully read whatever arguments have been put forward in order to minimize the awkward effects of pregnancy upon tuberculosis I came to the conclusion that the principal causes for such divergence of opinions lay in the somewhat loose conditions of our diagnostic criteria. It has been one of the lessons of the great war that we have realized how necessary it is that we should revise those criteria, and that we should adjust our clinical methods of diagnosis to the far-reaching discoveries which, at the beginning of the present century, have so completely transformed our ideas concerning the pathology of tuberculosis. Since we have learned to discriminate between tuberculous infection of the adult, which in civilized countries is nearly universal, and tuberculous disease, which develops only in a small proportion of the infected adults, we are no longer justified in endeavouring, as we formerly did, to make the diagnosis and the early treatment of tuberculosis coincide as nearly as possible with the initial stage of infection. We must rely, therefore, less on general and functional symptoms, to which such a decisive importance was attached in the near past, than on positive signs—the demonstration of a definite lesion on an x-ray plate and of tubercle bacilli in the sputum being, as a general rule, the most fundamental of those signs. Previous to the war we all complained that a large proportion of tuberculous disease of the lung was overlooked and mistaken for some other morbid condition. That this is still going on we sadly know, but to many of us it came as a surprise that, by using more correct diagnostic criteria, we should find that the reverse error was by no means less common—namely, that a considerable proportion of morbid conditions, some very harmless, some serious, were in ordinary practice mistaken for tuberculosis and unduly treated as such.

Now if we read some of the papers where the association of tuberculosis with pregnancy is regarded as being only exceptionally harmful, we may observe that the diagnostic criteria used by their authors are generally very disputable, they are of a vague and purely symptomatic character, and we get the impression that, among the favourable cases, a few only were really and positively tuberculous. When, however, statistics are based upon reliable diagnostic criteria they invariably show that pregnancy in a tuberculous woman leads to an aggravation of symptoms, to the extension of existing lesions, to the production of fresh ones, and to the flaring up of those which were quiescent. Death may occur during the course of pregnancy or after a premature or mature birth. The mother may survive confinement for some time, but her condition has become definitely and permanently worse. The few exceptions to this rule concern women who had a markedly fibrotic and obviously mild form of tuberculosis.

Summing up last year with my assistant, Dr. Andler, the cases which had been followed in my hospital department since 1919, concerning women who, being already affected with some form of lung tuberculosis, had become pregnant, I found a total number of 52. Among them 12 had only one lung affected, 40 had a bilateral tuberculosis. The fate of these 52 women can be summarized as follows:

Condition unchanged, but incurable	8=15.3%
Condition worse	44=84.6%
Death after one year	19=36.5%
Death after two years	26=50.0%

In 2 cases the women died during the last three months of pregnancy—one woman died during the first week after confinement, 6 died during the first three months after confinement. I presume that almost all of the "worse" cases have since passed into the "deceased" group. The symptoms and signs of an aggravation of the tuberculous process may appear at any time during the course of pregnancy. A considerable number of cases turn suddenly worse immediately after confinement.

But this does not give us an insight into the more important side of the problem, the largest proportion of facts where tuberculosis is associated with pregnancy is not made up of cases where an already tuberculous woman becomes pregnant. For obvious reasons such cases are rather seldom observed. A woman who knows that she is affected with tuberculosis, or who simply feels in a condition of bad health, generally avoids pregnancy.

We meet much more frequently with women who previous to becoming pregnant, were in good health, and in whom the symptoms and signs of tuberculosis of the lungs appear either during the course of pregnancy or immediately after confinement, or during the first three or four months following confinement. In the statistical survey previously mentioned I find 117 such cases.

In a first group of 11 women the generally acute and sudden onset of tuberculosis was coincident with the beginning of pregnancy.

Condition unchanged	2
Condition worse	9
Death at end of first year	6
Death at end of second year	7

In a second group we find 22 women who became consumptive during the first three months of pregnancy.

Condition unchanged	2
Condition worse	20
Death at end of first year	9
Death at end of second year	13

In a third group of 22 women the onset of tuberculosis occurred in the last six months of pregnancy.

Condition unchanged	2
Condition worse	20
Death at end of first year	7
Death at end of second year	12
Death after the second year	16

If we sum up these three groups, including all the cases where the onset of tuberculosis occurred during the course of pregnancy, we get the following figures:

Condition unchanged	6=10.9%
Condition worse	49=89.09%
Death rate after one year	41.8%
Death rate after two years	58.1%

Our fourth and last group concerns 62 cases, where the onset of tuberculosis followed confinement either immediately or during the first six months. There is no doubt that the previous pregnancy was a determining factor in the incidence of tuberculosis in such cases, 55 out of them had both lungs affected, 7 only one, 12 had died at the end of the first year, 5 more at the end of the second year, 7 more still later, 8 only no more or less quiescent. Therefore, among the 117 cases where tuberculosis began either during pregnancy or shortly after pregnancy, 60 (51.2 per cent) died after two years, 43 (36.7 per cent) were still alive in a severe condition, leaving little hope of recovery, a large number of these have probably died since this survey was made. But we must not forget that even in the 14 temporarily arrested or quiescent cases, representing 11.9 per cent of the total, pregnancy was the determining cause in the onset of tuberculosis.

It is a matter of common observation among physicians who specialize in the treatment of consumption that there is no circumstance more likely to disturb the healing process determined by a sufficient in and rest cure, or by a successful artificial pneumothorax, than the occurrence of pregnancy. The flaring up of the disease may be only temporary, it may be limited to the reappearance of some bacilli in the sputum, which had remained sterile for a long period before, to a transient loss of weight with abnormal temperatures. But it may also be, and it too often is, quite serious, characterized by the rapid extension of the existing lesions or by the appearance of severe lesions in the hitherto sound contralateral lung. Many a woman who had the most favourable prospects for making a complete recovery has lost all her chances and has died because of an intervening pregnancy. Conversely, I know of no better criterion of complete and permanent healing of a once confirmed tuberculous lesion in a woman than the fact that she has been able to bear a child without having to suffer from any recurrence of symptoms or signs of her lung disease.

How are these causal relations between pregnancy and tuberculosis to be explained? How does it come about that pregnancy not only gives an already existing tuberculous lesion but is also a determining factor in the onset of tuberculosis in women who previous to their pregnancy, had been in perfect health. We know very little concerning that aspect of the question as we know very little in general concerning the causes which more or less suddenly, turn a healthy adult having a normal tuberculin skin reaction into a tuberculous patient. But I think we cannot but give due consideration to an important fact which has been ascertained by many a student of the subject—namely, that there is a comparatively high proportion of pregnant women who lose their capacity of giving a positive skin reaction to tuberculin and recover it only some time after confinement. This condition of anergy is not universal in pregnancy, as it is in measles, for instance. According to Nohacourt and Paraf, it is found in 15 to 20 per cent of pregnant women during the last three months of pregnancy. Other workers give a somewhat higher percentage. If, as we have good reason to believe, the temporary loss of the allergic state acquired by civilized man during his childhood through a mild primary infection means that his specific resistance to tuberculosis has given way, we are led to think that pregnancy is one among the causes which diminish the specific allergic resistance to tuberculosis. Why it should be so is far from being clear.

Nevertheless I would like to mention in that respect the very extensive and prolonged studies which have been made concerning that difficult problem by one of my co-workers Dr J. Coulaud of Paris. He has succeeded in showing that pregnancy and confinement are not the only phases in a woman's life which are able to determine a temporary allergic condition. Abortion has the same effect. The advent of puberty may act in a similar way and in some women even premenstrual period is accompanied by a more or less noteworthy failing of the skin reaction. The menopause may also produce a transient anergic condition and so does operative castration. It is certainly interesting to note that the variations in the reaction of the skin to tuberculin to a certain extent run parallel with some characteristic features of female tuberculosis. The periodical and on the whole unfavourable influence of menstruation upon the symptoms of consumption is a well known fact. Less well known, perhaps is the fact that, among the cases of tuberculosis occurring late in life, a considerable proportion began at the time of the menopause. Coulaud has also collected quite a number of cases where the onset of tuberculosis occurred shortly after a double ovariectomy.

According to his views which he has supported with a great number of carefully conducted animal experiments the link between all these facts should be looked for in the hyperactivity of the thyroid gland, which normally accompanies almost every phase of the female sexual life. Having had an opportunity for studying the morbidity distribution of tuberculosis in a region in the north of France in which goitre is prevalent, he found that people affected with goitre and having an abnormally low thyroid activity were only exceptionally affected with tuberculosis and then only in a mild form. There should be, therefore, some relation between the activity of the thyroid gland and the susceptibility to tuberculous disease. This problem of the interrelation between functional disturbances of the thyroid and the course of tuberculosis has been approached in many ways by several clinicians. It is a very intricate one, and I do not propose to discuss it here. My aim was only to mention how Coulaud's studies show it to be connected with the problem of tuberculosis and pregnancy.

Let us now turn to a more practical aspect of the question. The coincidence of pregnancy with tuberculosis being so ominous and having such fatal consequences, what can we do in order to lessen its dangers? Abortion has been advocated by several obstetricians and physicians as being the only way to save the life of the mother. Some have even gone as far as recommending total hysterectomy, arguing that by so doing the possibility of such a coincidence occurring in the future is prevented. Both practices have met with considerable opposition. For my own part,

I rather side with the opponent, for many reasons. In the first instance, I am convinced that should abortion be encouraged in these circumstances it would lead to many regrettable excesses. Not to mention the cases where unjustifiable abortion would be ruthlessly practised by unscrupulous people and the pretence of tuberculosis is a figment, I feel certain that many a pregnancy would be honestly but unduly interrupted because of that loose condition of the diagnostic criteria of tuberculosis to which I referred above. Personally I have been a led on some occasions to give an opinion regarding the advisability of inducing abortion in women who were regarded as tuberculous and in whom I could find absolutely no reasonable evidence of tuberculosis. On the other hand I do not think it has been sufficiently proved at the present time that abortion is really efficient in arresting the course of tuberculosis of the lungs determined or aggravated by pregnancy. Some very satisfactory results have been published, but these are few in number. For my part, I have seen spontaneous abortion influence tuberculosis just as unfavourably as confinement. The advocates of abortion all agree that it should be practised only during the first three months of pregnancy, because after that period it always leads to an aggravation of the lung symptoms. This of course, limits the intervention to a small proportion of cases, but, even within these limits I think we should be exceedingly cautious in recommending it.

Artificial pneumothorax has been—at first timidly and seldom, but lately with much greater frequency—applied to pregnant tuberculous women. That it interferes in no way with the favourable course of pregnancy or labour has been very conclusively proved. It has therefore, the considerable advantage over abortion that it saves the child's life in a large proportion of cases. It ought to be tried whenever it is possible—that is, when the lesions are one-sided and there are no extensive pleural adhesions.

From June 1919 up to January 1st 1926 the influence of artificial pneumothorax upon tuberculosis previous to or coincident with pregnancy or beginning shortly after confinement has been studied in 53 cases in my hospital department.

In a first group we find 15 women who came to us after confinement, having a lung tuberculosis which had been either aggravated or determined by pregnancy. The collapse treatment was begun not less than two months after confinement, with the following result:

Clinically well	5
Treatment unnecessary	2
Deceased	8

In a second group we have 25 women who had their artificial pneumothorax established during the course of pregnancy. The results were as follows:

Clinically well	6
Situation unchanged	3
Worse	6
Deceased	10

In these two groups the results are far from being brilliant, although I doubt very much whether abortion could have shown a better record. The proportion of successful cases is only 27.5 per cent whereas it is 52 per cent among the 476 women treated with artificial pneumothorax for chronic common unilateral tuberculosis of the lung, outside of any connexion whatever with pregnancy. This certainly illustrates the peculiarly malignant character of tuberculosis associated with pregnancy. The probability of recovery through lung collapse is twice as great for non-pregnant as compared with pregnant women. It shows most clearly that pregnancy is a decidedly aggravating factor in tuberculosis of the lung.

If on the contrary we turn to our third group—namely 18 women who were already treated with artificial pneumothorax when they became pregnant—the encouraging proportion of success is:

Clinically well	14
Deceased	4

The older the collapse the better the result. This I think is one of the most drastic indications which could be given to support the use of artificial pneumothorax as really an efficient treatment of consumption, and this is

able to restore patients, who formerly had to be given up as hopeless cases, to all the privileges of health. As I said before, there is no better test of healing in a tuberculous woman than the capacity of bearing children without having any recurrence of the lung disease. If a woman who has been successfully treated by artificial pneumothorax for tuberculosis of the lung has become clinically well, if she has been, say, two years without expectorating bacilli, if her temperature is permanently normal, there is no person who she should not be allowed to become pregnant, but I always insist that the collapse should be maintained during the first trial, and for at least six months after confinement. I also insist that the mother should not nurse her baby. I have now on record, beside my hospital cases, several young married women in my private practice who have been wise enough, being treated by artificial pneumothorax, to defer pregnancy until I thought that collapse had lasted long enough to make them safe, and who have in due time borne healthy children. On no single occasion have I had to regret it. I should also mention four cases of girls whom I had treated successfully by artificial pneumothorax for severe one-sided lung tuberculosis, and who married and bore children with my approval after their collapse had been abandoned for two or three years. They have all remained perfectly well. Here we have what may be called the sunny side of the interrelations between tuberculosis and pregnancy. The dark side, as you have seen, is dark enough.

### III—VENEREAL DISEASES IN PREGNANCY

BY

F. J. BROWNE, M.D., D.Sc., F.R.C.S. Ed.,

Professor of Obstetric Medicine, University of London, Director of Obstetric Unit, and Obstetric Surgeon, University College Hospital, London.

Those in charge of the arrangements of this Section are to be congratulated on including this as one of the subjects for discussion. There are few subjects in obstetrics that cause more anxiety to the man in general practice, and none in regard to which he obtains less assistance from reading the current textbooks, either on midwifery or venereal diseases.

#### SYPHILIS IN PREGNANCY

I shall deal with syphilis under four headings: (1) Frequency, (2) Diagnosis, (3) Treatment, (4) the Outlook.

##### Frequency

In the ante-natal clinic of the Edinburgh Royal Maternity Hospital, of which I was in charge for some years, Miss Gladys H. Dodds found a positive Wassermann reaction in 130 of 2,000 (6.5 per cent.) consecutive cases examined. In 3.6 per cent of these the reaction was triple positive. In 0.3 per cent it was moderately strongly positive, in 1.4 per cent it was weakly positive, and in 0.8 per cent the reaction was doubtfully positive. In 0.3 per cent the serum was anti-complementary, and, finally, in 0.7 per cent the reaction was negative, but the patients were considered from other evidence to be syphilitic.

These figures show that in an ordinary ante-natal clinic the frequency of syphilis is at most about 7 per cent.

##### Diagnosis

In diagnosis attention should be directed to the following points:

1. *The Clinical History*—In about 70 per cent of syphilitic primigravidae a history of clinical evidence of syphilis will be obtained. In syphilitic multiparae such information is only obtainable in about 30 per cent. There is a good deal of evidence to show that the reason for this absence of history of syphilis in multiparae is not that signs of syphilis have never been present, but that they have been forgotten or are denied. I have discussed this fully elsewhere, but have since then met with a striking example in illustration. A letter was sent from the venereal diseases clinic of the Edinburgh Royal Infirmary with a letter which stated that her previous pregnancy two years before had ended in a miscarriage, and that just before the miscarriage she had

come under observation, suffering from the usual signs of secondary syphilis—namely, rash, sore throat, mucous patches, and condylomata, with a triple positive Wassermann reaction. On questioning her most carefully regarding her past history I found that she denied that any such signs had ever been present.

2. *Clinical Signs of Past Syphilis*—These may be found on careful examination in the form of scars of healed gummatous, especially about the calves and knees, leucoderma, etc.

3. *Obstetric History*—A history of repeated stillbirths, abortions, or neo-natal deaths, without obvious causes to account for them, such as nephritis or birth injury, should arouse suspicion.

4. *The Wassermann Reaction*—A strongly positive Wassermann reaction is, in my opinion, certain evidence of syphilis. I do not believe that the toxæmia of pregnancy can give rise to it, at least I have never seen an example of that. On the other hand, a patient may have a negative reaction and yet be syphilitic and give birth to syphilitic children. It is important that the practitioner should recognize this. It is only fair to state in this connexion that I have never met with a case in which a mother with a negative Wassermann reaction gave birth to a foetus the organs of which contained spirochaetes.

5. *Examination of the Product of Conception*—This is perhaps the most valuable method of diagnosis at our disposal, and it is strange that it should be almost entirely overlooked by those who write textbooks. In one of the most recent and excellent textbooks on venereal diseases, for example, it is not even referred to. Evidence may be found in (a) the placenta, (b) the cord, (c) the foetus.

*The Placenta*—The classical characters of the syphilitic placenta are well known, its pale, greyish, bulky appearance is described in every midwifery textbook. What is less well known is that these typical appearances are only found in the placenta of the macerated foetus, and that if the foetus is born alive, though syphilitic, the placenta may seem perfectly healthy both to naked-eye and microscopic examination. Why is this? Because intra-uterine death of the foetus in syphilis is directly due to obliteration of the foetal capillaries in the villi. This obliteration is brought about by subacute inflammation, the end-result of which is fibrosis causing enlargement of the individual villi. If the fibrosis is extensive the foetus dies and is born macerated, if the fibrosis is less marked the foetus is born alive, and the placenta shows little or no change from normal.

The normal placenta at term weighs less than one-fourth of the foetal body weight. If a placenta at term, or in the ninth month, weighs one-fourth or more of the body weight it is almost certainly syphilitic.

A placenta, however, with a normal weight ratio does not necessarily exclude syphilis. That is because a healthy placenta at term may weigh as little as one-tenth or even one-fifteenth of the foetal body weight. Even if such a small placenta were affected by syphilis the consequent enlargement might not be sufficient to raise its weight ratio above the normal limit.

Although the microscopic examination of the syphilitic placenta usually reveals nothing absolutely diagnostic, yet the appearances are generally highly suggestive—namely, the enlarged cellular avascular villi with the correspondingly diminished intervillous spaces.

*The Cord*—Most valuable evidence may be obtained from the cord. The piece of cord for examination must be taken as close to the foetal end as possible. The usual change is round-cell infiltration around, and in the walls of, the umbilical vein. The spirochaete may be demonstrated in the tunica intima by appropriate staining methods. This diagnosis of syphilis from the cord is particularly valuable, as it is available when the foetus is born alive and apparently healthy. It must, however, be emphasized that even when syphilis is present the cord may be quite normal.

*The Foetus*—If the foetus is macerated this is in itself suspicious, as one-third of all macerated foetuses are syphilitic.

In the examination of the macerated foetus four points will be of assistance: (a) the liver, (b) the spleen, (c) the epiphyses, (d) the presence of the spirochaete in the organs.

**The Liver**—The normal foetal liver weighs about one-twentieth of the body weight. If it weighs one-twelfth or over it is almost certainly syphilitic. At the same time it should be remembered that, as in the case of the placenta and for the same reason, it may be less than one-twelfth—for example, one-twentieth or one twenty fifth, and yet be syphilitic.

**The Spleen**—A normal foetal spleen may weigh 1/150th of the body weight. If it weighs more than this it is almost certainly syphilitic. Again, as in the case of the liver and placenta, a normal weight ratio does not exclude syphilis. Such exceptions, however, are rarer than in the case of the liver and placenta. An enlarged spleen is a most valuable sign of foetal syphilis.

**Chondro-Lipofusis**—The jagged, irregular chondro-epiphyseal junction is well known and requires no further description. In doubtful cases it may be demonstrated microscopically.

**Presence of Spirochaetes**—These are, as a rule, best demonstrated in the liver, spleen, suprarenal gland, and kidney, either by dark-ground examination or by the Levaditi method of silver staining for permanent specimens. Their presence is, of course, absolute evidence of syphilis.

**The Fresh Dead Fetus, or the Dead Infant**—If the foetus is expelled dead but in a fresh condition, or if the child dies, its organs are available for microscopic examination. The changes are best found in the liver lungs, thyroid gland, and pancreas, and are, generally speaking, of the nature of subacute inflammation and fibrosis. I shall not refer to these, as they have been fully described elsewhere.

#### Treatment

In treatment four main principles should be borne in mind.

(a) It should commence as early in pregnancy as possible or, better still, a full curative course of treatment should be completed before pregnancy is allowed.

(b) The patient should be treated by arsenical compounds in every pregnancy—no matter whether she seems cured or not.

(c) Treatment may be continued with perfect safety up till the time of confinement.

(d) Arsenic and mercury, or bismuth should not be combined in treatment, on account of their tendency to damage the kidneys. In this respect bismuth and mercury are more dangerous than arsenic, if there is no albuminuria. However, they may be given alternately. If there is albuminuria it may be necessary to stop all treatment, except by potassium iodide, so long as the albuminuria lasts. In some rare cases the albuminuria may be due to syphilis, and then arsenical treatment carefully watched, may be tried.

**Method of Treatment**—The best results are obtained by the use of nonarsenobenzol intravenously, starting with a small dose of 0.3 or 0.45 gram, and increasing carefully to 0.6 or 0.75 gram. The injections should be given once weekly, and continued until six or eight doses are given. A careful watch should be kept for albuminuria. After this there should be a month's interval, during which mercury, in the form of 10 minims of grey oil (corresponding to 1 grain of metallic mercury), is administered intramuscularly into the buttock once weekly, the site of injection being massaged so as to aid absorption. Intramuscular bismuth—preferably one of the insoluble compounds such as hiocel—may be given as an alternative twice weekly. In the case of both bismuth and mercury treatment the most careful attention should be paid to the state of the teeth. These courses of arsenic and mercury or bismuth should be given alternately until the end of pregnancy. After delivery treatment should be continued, a course of treatment of eighteen months duration as outlined above, is the minimum, and it is well to continue treatment for a year after all tests are negative. In the case of husbands with old and probably cured syphilis it is well to advise a prophylactic course as a safety measure for some weeks preceding marriage. Finally it must be emphasized that there is no proof of the cure of syphilis except re-infection, and that antisyphilitic treatment should be repeated in every pregnancy, no matter whether apparently cured or not.

#### The Outlook

What is the outlook for obtaining a healthy child by such measures?

The most complete figures with which I am acquainted are those of Boas and Cammelfort, who have followed up some of the children for as long as fifteen years. The following table gives the main facts.

Treatment of Mother	No. of Children	Syphilitic Infant	Healed by Infant	Percentage—	
				Survived	Healed
Syphilis not treated	21	14	7	9.5	3.5
Mercury before pregnancy	87	73	9	9.0	1.0
No treatment during pregnancy					
Salvarsan before pregnancy	15	12	3	80.0	0.0
No treatment during pregnancy					
Mercury during pregnancy	111	80	31	77.0	2.0
Salvarsan before pregnancy	20	7	19	47.0	7.0
Mercury during pregnancy					
Salvarsan during pregnancy	68	13	73	90.0	81.0
Salvarsan before pregnancy	7	1	6	17.0	20.0
Salvarsan during pregnancy					

The best results are therefore obtained from salvarsan both before and during pregnancy, but even with that no guarantee can be given that the child will not be a congenital syphilitic.

#### GONORRHOEA IN PREGNANCY

My experience of gonorrhoea in pregnancy is that it does not often give rise to acute symptoms such as cystitis, if it does the diagnosis is fairly obvious, and treatment in the acute stages is almost standardized—namely rest in bed, prevention of spread of infection by vaginal protection, hot antiseptic Sitz baths, carbohydrate diet and plenty of fluid and, as soon as the patient can bear it, treatment by local applications in the lithotomy position. Arthritis is, in my experience the most common complication, and its treatment often demands much circumspection.

I shall deal here with the more common subacute or chronic infection, its methods of diagnosis and treatment. Some anatomical peculiarities of the female genital tract explain why primary infection is limited to certain areas. The vulva and vagina are covered by a squamous epithelium, which in the adult female is very resistant to the entrance of the gonococcus. But there are about the vulva certain vulnerable areas which are not so protected and through which the gonococcus can therefore enter and set up infection. These are (1) the duct and gland of Bartholin, (2) the urethra and periurethral gland, especially Skene's glands. Therefore while we do not find a primary vulva in the adult, we often get a Bartholin's and a urethritis. The cervix is a third vulnerable area in the lower genital tract. Its canal is lined by columnar epithelium, between the cells of which the gonococcus can easily penetrate into the deeper cervical tissue. From the canal open into the racemose glands of the cervix and into warm moist gonococcus can easily enter and he safely enclosed beyond the reach of local applications. The cervical infection sets up cervicitis—the well known cervical erosion or crater with discharge of mucopurulent mucus and is accompanied by vaginitis or vulvitis and both vagina and vulva become inflamed and swollen.

#### How to Examine a Case of Suspected Cervicitis

Examination can only be properly carried out with the patient in the lithotomy position and in a good light. In private practice the position can easily be obtained with a pair of lithotomy props. The gland of Bartholin is first examined by picking up the labium majus at the

junction of its posterior and middle thirds between the finger and thumb. Normally the gland is not palpable. If any enlargement is felt it is almost invariably due to gonorrhoea. It may, if only slight enlargement and induration are present, be caused by very old-standing infection.

Next the orifice of the duct should be examined, this is a pin-point opening at the junction of the hymen with the labium minus, near the posterior end of the latter. An area of rose redness spreading on to the adjacent mucosa is suspicious, but it is not so strong evidence as enlargement of the gland. It may be possible to squeeze a little pus from the duct, if so, it should be spread on a glass slide and allowed to dry in air, being afterwards sent to a bacteriologist for examination.

The urethra should next be examined, care being taken that the patient has not passed urine for three hours. The urethra should be milked from the neck of the bladder downwards to the external meatus, and if pus is obtained a smear, and possibly a culture, should be taken. The absence of Bartholinitis and urethritis, however, by no means excludes gonorrhoea.

The cervix should then be examined, preferably using a bivalve speculum, which gives the best exposure. In acute infection it usually appears purple and congested, and bleeds on touching. In more chronic cases there may be actual desquamation of epithelium, the well known erosion. Often it is bathed in muco-purulent secretion. A swab must be taken from the cervical canal, care being taken not to trespass above the internal os. Smear or culture is again made. The cervix, however, may look perfectly normal, and yet gonococci may be obtained from the canal. A swab merely from the vagina is generally of no value whatever in excluding gonorrhoea.

What is the value of a negative smear? A negative smear is of little value in diagnosis and it should be repeated on at least three successive occasions. The gonococcus is most likely to be found just after a period, but this test is not available in pregnancy. We may, however, give a provocative injection of 200 million gonococcal vaccine and examine the discharge twenty-four, forty-eight, and seventy-two hours later. If in doubt regarding the diagnosis it is always better to treat the case as if it were gonorrhoeal.

#### Treatment

The multiplicity of remedies in gonorrhoea is evidence that none is very efficient. Almost the weakest antiseptic will kill the gonococci; it can be brought into contact with it, but the organisms are entrenched in the peri-urethral or cervical glands beyond the reach of most local applications.

The patient should be in the same position as for diagnosis and the external genitals cleansed with a solution of lysol or mercury perchloride. With a bivalve speculum the cervix is exposed, and from it and the vagina all mucus is wiped, either with a dry sterile swab or with sodium bicarbonate solution. The latter removes mucus better and leaves a clean surface. The position and vagina should now be swabbed with a silver or other preparation, such as 10 per cent protargol or neoprotosil, or 1 per cent picric acid in spirit. After trying many of these remedies I think as good results are obtained by swabbing with saline solution. In pregnancy the parts must be handled very carefully, and special care be taken in making application to the cervical canal, lest premature labour be induced. One may, however, very gently swab the canal, using a Playfair's probe dressed with cotton-wool dipped in the selected solution, and rotating the probe carefully. It is rare to find urethritis persisting at this stage, but if it is, it may be necessary to inject, with a glass syringe carrying in turn nozzle, a silver or other preparation such as 1 per cent picric acid or 1 in 1,000 resorcin, or 1 per cent silver protein, or, as an alternative, medicated methyl bougies may be used containing 10 per cent neoprotosil or any similar preparation. Sometimes there is a chronic infection of Skene's ducts, and it is necessary to inject them by means of a blunt-pointed hypodermic needle or they may be destroyed with a cautery. Finally, the cervix and vagina are dusted with an astringent dusting powder such as dermatol, which helps to keep the

surface dry. Twice a week is generally sufficient for local treatment, and in most cases there is no need for rest in bed.

Detoxicated vaccines are of considerable assistance in clearing up the discharge, starting with a dose of 5,000 million, repeating once weekly, and gradually increasing to 50,000 million, which may be continued till the end of pregnancy. I have no experience of ionization or diathermy in treatment, neither do I think they would be applicable in pregnancy.

With the treatment outlined above it is almost always possible to get the discharge cleared up in a few weeks and before delivery occurs. Very few of the cases are troublesome in the puerperium.

Douching is, in my opinion, dangerous, and less effective than the method above described, and should have no place in the treatment of gonorrhoea in pregnancy.

Finally, it must be emphasized that the only absolute test of cure of gonorrhoea is the absence of the power to reinfect the male, and that treatment must be continued after pregnancy is over until at least all clinical evidence of disease is eradicated.

#### ARRANGEMENTS FOR TREATMENT

The following principles may be laid down as the minimum necessary for the proper diagnosis and treatment of venereal disease in pregnancy.

- 1 A routine Wassermann test should be carried out on every patient at the first visit to the antenatal clinic, treatment being started immediately a positive diagnosis of syphilis is made.
- 2 The treatment centre should be in the maternity hospital, special days being set apart for that purpose. Pregnant women with venereal disease are generally innocent victims, and resent attendance at an ordinary venereal disease department amongst patients of doubtful character.
- 3 The treatment should be carried out by a woman expert who may or may not be a member of the maternity hospital staff. It is probably preferable that she should be the person responsible for the treatment of women in the ordinary venereal disease clinic. She would then have charge of the mother also after delivery and until discharged child.
- 4 Antenatal beds should be provided in the maternity hospital for women suffering from venereal disease. They should not be labelled "V.D." beds, but simply "antenatal." In the Edinburgh antenatal department of 25 antenatal beds 13 were devoted to venereal cases. The beds were always referred to (amongst the staff) as "D.K. beds" and the department is the "D.K. department." To the patients it was simply the "antenatal department," although the venereal cases were in separate wards with a separate nursing staff. Such beds are necessary for—

- (a) Cases of acute gonorrhoea and those ill with complications such as arthritis.
  - (b) Cases living too far away to attend as outpatients.
  - (c) Cases who, because of the advanced stage of pregnancy, cannot attend as outpatients with sufficient regularity.
  - (d) Patients suffering from venereal disease plus some of the ordinary non-venereal complications of pregnancy—for example, albuminuria—requiring indoor treatment.
- 5 All cases suffering from severe vaginal discharge should be treated in the clinic, whether the gonococcus has been found or not. If only cases of proved gonorrhoea are treated the majority will be missed, and if the department is not labelled "V.D." no stigma attaches to treatment there.
  - 6 Attached to every maternity hospital there should be a pathologist who is expert in the examination of the products of conception for evidence of syphilis. Unless this is done invaluable evidence—often the only evidence—will be missed.
  - 7 At the end of each month or oftener, a list of congenital syphilitic infants or of suspected cases requiring observation should be sent to the child welfare medical officer. He will, of course, keep in touch with the children, examine them at intervals, and have treatment carried out if necessary.
  - 8 The maternity hospital venereal disease clinic should be in close contact with the general venereal disease clinic of the hospital or town in which it is situated. After delivery it will generally be found best that treatment should be continued in the general clinic. This continuity of contact will generally be easy if the treatment in each is carried out by the same medical officer.
  - 9 Any complete scheme demands the appointment of a nurse who will follow up patients failing to attend regularly for treatment. It is usually unnecessary to tell patients that they

are suffer from syphilis or gonorrhoea but if they fail to attend regularly or refuse to undergo treatment it is often less to do so and a quiet talk with the patient and perhaps also with her husband usually has a salutary effect.

10 Co-operation with the venerable diverse centre will ensure getting in touch with the husband and treating him as well as the mother.

The scheme I have outlined is practically that which has been in operation in Edinburgh since 1920

In conclusion I feel it my duty once again to advocate the compulsory notification of pregnancy at an early period say the third or fourth month. Only in that way will all cases of syphilis in pregnancy be discovered & such an early period that effective treatment may be carried out. If all syphilitic pregnancies ended in abortion or the birth of macerated foetuses such early notification would not matter. Diagnosis could be made at delivery and treatment carried out before and during the next pregnancy. But such a happy termination does not always take place. A baby may be born alive and continue to live with congenital syphilis and grow up to be a burden to itself and the community. As Professor Karl Pearson says "We persecute parents for cruelty to their children, but what is a greater cruelty than bringing children into the world of whom we can predict on the average that a certain number will suffer from incurable disease and that others, without being afflicted, will transmit that disease to the next generation."

PREFACE.

#### IV—CARDIAC DISEASE IN PREGNANCY AND LABOUR

GIBBON FitzGIBBON M.D. B.Ch. F.R.C.P.  
Consulting Gynaecologist Retired Retina Hospital Dublin

During my mastership of the Rotunda Hospital I find I have recorded 22 cases of cardiac disease complicating pregnancy and labour out of a total of 13,000 confinements. This gives an incidence of 0.16 per cent. These are all cases of loss of compensation and delivery. In the last two years a result of ante-natal supervision, the number of cases has increased, giving a percentage of 0.33.

## Mortality

Of the 22 patients 5 died a mortality of 22.7 per cent but omitting a case of acute vegetative endocarditis the mortality is 19 per cent in chronic valvular lesions. Three deaths were of patients who were admitted with loss of compensation labour set in before the cardiac state showed any improvement. One of these patients was a primigravida aged 30 thirty-seven weeks pregnant who delivered herself rapidly of a macerated foetus and died in a few hours. The other two patients were multiparae a 3 para aged 36 twenty-eight weeks and she died thirty-two days after delivery and a 4 para aged 30 twenty-four weeks pregnant with aneurism fibrillation which never altered she delivered herself of a macerated foetus and died three days later. The fourth death was that of a 3 para aged 33 admitted at thirty-four weeks she improved under treatment for three weeks when commencing developed. The cardiac state relapsed when digitalis was stopped she was delivered by section during decompensation and although improving for a few days died nine days after delivery. The fifth death was that of a primigravida aged 19 thirty-four weeks pregnant who died a few hours after spontaneous delivery and was found to have an acute endocarditis with vegetation on the mitral and aortic valve. Two all the deaths were of patients who were delivered while the heart was in a state of acute decompensation.

Counting the case of acute endocarditis there were 10 patients of these pregnancies complicated by cardiac disease. Five of these patients went to term and decompensation appeared to be precipitated by the onset of labour they all delivered themselves, two being completed by forceps in the second stage, all recovered and all the infants were born alive. The age of the patients were 19, 22, 22, 22 and 23 years, all being multiparae, the last case a primigravida as the cardiac lesion had been acquired since her previous confinement six years before.

Three primigravidae developed a failure of compensation during pregnancy—one case at the thirty-second week, one at the thirty-seventh week and three at the thirty-eighth week. The three cases at the thirty-fourth week were pondered to cardiac uterine were secured in hospital and delivered there, i.e. of living infants by spontaneous labour one aided by forceps at the thirty-sixth, thirty-seventh and thirty-eighth week of pregnancy. The patient at thirty-eighth week had no compensation for several

days without treatment and fell into labour after two days treatment without any improvement in the cardiac state. She delivered herself of a macerated foetus after a hardly noticeable labour of two and a half hours and died ten hours later. The patient at thirty-two weeks had failure but recovered no treatment until after labour started. She delivered herself in two hours of a small living infant. Cardiac condition was very low over several months but finally compensation was established.

Of the 11 multiparae only 3 went to term and the loss of compensation appeared to be the result of the onset of labour. Two of these patients, aged 23 and 24, were in their second pregnancy and one aged 35 was in her third pregnancy; they all delivered themselves of living infants and subsequent convalescence was satisfactory.

Eight multiparae developed loss of compensation during pregnancy; three received no treatment before the onset of labor, while the other five were treated at ages 35, twenty-eight week pregnant did without improving thirty-two days after delivery. The other two recovered both were aged 40 one a para at the twentieth week withortic stenosis causing fainting rather than decompensation the other a 17 para at the twentieth week but in only her third pregnancy to carry beyond the sixteenth week with double mitral murmur and enormous hypertrophy of the heart.

A 4 para aged 30 twenty four week pregnant had failure for some days but received no treatment until in a state of irregular fibrillation she showed no response to treatment for two days then delivered herself and died three days later without any improvement.

any improvement  
 Four multiparae responded to treatment. A 2-para aged 35 (twenty-four weeks pregnant) improved following labour at thirty weeks and delivered herself. Compensation had been fairly well re-established but again failed during labour and for a few days then convalesced at home. A 3-para (1 abortion) aged 31 had failure at thirty-four weeks responded well to treatment and went home but returned at thirty-seven weeks severely decompensated and in labour she delivered herself in two hours but was in a critical state for the next two days after which she improved steadily. A 3-para aged 33 improved but at thirty-seven weeks digitalis had to be stopped and failure recurred. She was delivered by section improved for a few days but relapsed and died nine days after delivery. A 3-para aged 39 at thirty-two weeks improved but the membranes ruptured at thirty-five weeks and at thirty-six weeks placenta praevia. She was delivered by section compensation was maintained.

### Prognose

The cases recorded above may be divided into three groups

- 1 When decompensation only occurs as a result of labour the prognosis is definitely good
- 2 When decompensation occurs during pregnancy and is treated early the prognosis is good
- 3 When decompensation occurs during pregnancy and is neglected until labour sets in the prognosis is bad

In the second group the prognosis is damaged by multiparity. The prognosis is better for cases under 25 than for those over 30 years of age.

*Results to the Foetus*—Of the 10 primigravida nine infants were born alive and all but one born at the thirty-second week survived. Of the 11 mult parae ten infants were born alive but only five survived the others being too premature. The prognosis for the infant is good provided decompensation is not selected during pregnancy while survival depends upon the maturity at time of birth.

## Conclusions

Decompensation does not tend to develop until the second half of pregnancy but is liable to set in progressively earlier in that half of pregnancy as the number of pregnancies and the age of the patient increase.

The majority (over 75 per cent) of primigravidae as a compensated cardiac lesion will carry to term and although one-third of them develop failure as a result of the onset of labour they deliver themselves of living infants and recover. In considering primigravidae it must be remembered that all the manipurians had delivered themselves successfully in their first labours.

When compensation fails in a primitive manner it can usually be reestablished and subsequently occur it is well borne

Only about 50 per cent of mulberry leaves are eaten during 1 hour than in the case of promastix.

When comparison fails during pre-trial preparation it is more difficult to reach a settlement in the grey area. There are very marked and real differences in labour which frequently occur and there is much greater probability of labour starting before a comparison is reached.

*Cases of Cardiac Disease in Pregnancy and Labour*

Case	Age	Pregnancy	Duration of Pregnancy when failure developed	Failure set in during labour	Labour started during loss of compensation	Compensation re established before labour	Period of Pregnancy at time of Delivery	Mode of Delivery	Result to Mother	Result to Infant	Cardiac Lesion
3	30	1	37 weeks	—	Yes	—	37 weeks	Spontaneous	Died	Macerated	Mitral stenosis
4	27	1	34 weeks	—	—	Yes	37 weeks	Spontaneous	Recovered	Alive	Mitral stenosis
6	24	1	32 weeks	—	Yes	—	32 weeks	Spontaneous	Recovered	A died	Double mitral
8	19	1	Term	Yes	—	—	Term	Spontaneous	Recovered	Alive	Double mitral
13	21	1	Term	Yes	—	—	Term	Forceps	Recovered	Alive	Double mitral
14	25	1	34 weeks	—	—	Yes	38 weeks	Forceps	Recovered	Alive	Aortic stenosis
17	34	1	34 weeks	—	—	Yes	36 weeks	Spontaneous	Recovered	Alive	Mitral regurgitation
18	24	1	Term	Yes	—	—	Term	Spontaneous	Recovered	Alive	Mitral stenosis
19	24	1	Term	Yes	—	—	Term	Spontaneous	Recovered	Alive	Mitral regurgitation
15	29	3 (1)	Term	Yes	—	—	Term	Forceps	Recovered	Alive	Aortic stenosis
1	36	3	28 weeks	—	Yes	—	23 weeks	Spontaneous	Died	A died	Double mitral
2	24	2	Term	Yes	—	—	Term	Spontaneous	Recovered	Alive	Mitral stenosis
5	33	3	34 weeks	—	Relapse	Yes	37 weeks	Caesarean section	Died	Alive	Double mitral
7	23	2	Term	Yes	—	—	Term	Spontaneous	Recovered	Alive	Double mitral
10	40	17 (3)	25 weeks	—	Yes	—	25 weeks	Spontaneous	Recovered	A, died	Double mitral
11	40	9	26 weeks	—	Yes	—	26 weeks	Spontaneous	Recovered	A, died	Aortic stenosis
12	30	3	32 weeks	—	—	Yes	35 weeks	Caesarean section	Recovered	A, died	Mitral stenosis
16	30	4	24 weeks	—	Yes	—	24 weeks	Spontaneous	Died	Macerated	?
20	31	5 (4)	34 weeks	—	—	Yes	37 weeks	Spontaneous	Recovered	Alive	Mitral stenosis
21	35	2	24 weeks	—	—	Yes	30 weeks	Spontaneous	Recovered	A died	Mitral regurgitation
22	35	3	Term	Yes	—	—	Term	Spontaneous	Recovered	Alive	Mitral regurgitation
9	19	1	31 weeks	—	Yes	—	34 weeks	Spontaneous	Died	Alive	Acute

When compensation has failed during pregnancy in any case and been re-established the pregnancy will practically never carry on beyond the thirty-sixth or thirty-seventh week.

Cardiac lesions tend to produce abortion and diminish the incidence of pregnancy. A woman who has decompensated during labour, and more particularly during pregnancy, is likely to abort in the first few months of a subsequent pregnancy, or to remain actually sterile.

This fact is not shown in my cases, but of the women I have treated I only know of two who have become pregnant, and these both aborted early.

*Conclusions as to Treatment*

Primigravida and multiparae who have never been decompensated during pregnancy may be allowed to continue through pregnancy and labour, with special care during the last eight and sixteen weeks respectively. If decompensation occurs during pregnancy, treatment should be directed only to re-establishing the cardiac function, and the patient should be kept at rest until after delivery. Primigravida may be allowed to go through labour, but multiparae will probably be best delivered by section at the thirty-sixth week and should be sterilized.

If decompensation occurs in a multipara before the thirtieth week the cardiac state should be re-established and then the pregnancy terminated, as the probability of the pregnancy reaching a period when the foetus will be likely to survive is practically nil. If labour sets in during the acute period of decompensation it is easy and rapid, and natural delivery will give as good a prospect as operative, the second stage should be shortened by forceps. A woman who has suffered from loss of compensation during labour should be kept at rest from the twenty-fourth week of a subsequent pregnancy, and this pregnancy should be terminated by section with sterilization at the thirty-sixth week.

A woman who has decompensated during pregnancy should never be allowed to continue another pregnancy, and such pregnancy would be best terminated by section and sterilization.

Induction of labour has no place in the treatment during decompensation, and at other times would be better preceded by section and sterilization as a means of terminating a pregnancy.

I have said nothing about the type of cardiac lesion, I think there is little to choose among them. Among my primigravida cases 3 suffered from mitral stenosis, 2 from mitral regurgitation, 3 from double mitral regurgitation, 1 from aortic stenosis, and 1 from acute endocarditis. Among the multiparae there were 3 cases of mitral stenosis, 2 of mitral regurgitation, 4 of double mitral regurgitation, 2 of aortic stenosis, and in one case the condition was unknown. My mortality was in mitral stenosis 1, in double mitral 2, 1 unknown, in acute endocarditis 1, in all delivery occurred during decompensation.

*DISCUSSION*

SIR EMERY MACLEIN (Cardiff) thought that individual experience of tuberculosis in pregnancy must be limited, except in the case of those working in special institutions. Two of the leading tuberculosis experts in Wales had expressed the view that Dr Rist was unduly pessimistic. Accurate diagnosis was extremely difficult, and many mistakes were made. A patient's progress could not safely be estimated by the physical signs. In some cases there was apparent improvement during pregnancy, and it was possible that the enlarged uterus produced some immobilization of the diaphragm, and thus acted favourably, especially if the bases of the lungs were involved. He thought that marriage need not be forbidden, but pregnancy should be avoided until three years had elapsed after the subsidence of all signs and symptoms. When pregnancy had occurred it should be allowed to continue so long as the larynx was not affected.

Professor LOUISE McILROY (London) did not agree with Professor Munro Keir's dismal view of the gravity of heart disease in pregnancy. She stressed the need for prolonged rest, and opposed the use of cardiac stimulants in the case of working women. Every heart case should be investigated by a cardiologist. She had established a cardiac

clinic in connexion with her ante-natal department, and only found it necessary to induce abortion in the rare cases when every other treatment had failed. She was agreeably surprised at the small number of Caesarean sections. Professor Kerr had mentioned she had abandoned sterilization for heart cases to a great extent and strongly disapproved of hysterectomy as the means to this end. Future pregnancy might be prevented by x rays or radium, or a contraceptive pessary might be used when further pregnancy was not advisable for a year or two. She thought that many patients with tuberculosis became worse through being discharged too soon from a sanatorium to bad home conditions for fear that labour might occur in the sanatorium.

Dr. Miss Macnicol (Edinburgh) thought that the outlook in syphilis with pregnancy was very good, but with gonorrhoea the reverse was the case. She urged that once a patient was known to have had syphilis the treatment should be given in every subsequent pregnancy even if the Wassermann reaction was negative. A history of repeated miscarriages was sufficient to justify a course of anti-syphilitic treatment. With more attention to cervical and vaginal discharges less would be heard of the occurrence of autogenous puerperal sepsis.

Dr. L. K. Macenzie (Tinn) gave his experiences as a rural practitioner far from specialist advice and help. Cases of mitral stenosis and aortic incompetence had caused him the greatest amount of worry. He thought that digitalis should be restricted to cases of fibrillation. The mental state of cardiac patients, especially in aortic disease, was sometimes particularly distressing.

Mr. R. H. Paramore (Rugby) explained the absence of higher blood pressure in normal pregnancy as being due to the rise of intra-abdominal pressure which increased the blood supply of the brain and extremities. It was the rise in pressure within the abdomen which led to an increased strain on the right side of the heart and hence, in disease, to failure of compensation. In cases where Caesarean section was called for on account of cardiac distress he suggested that hysterectomy would be advantageous by removing the products of involution, which otherwise might seriously affect the already embarrassed heart muscle.

Professor R. G. McKernon (Aberdeen) said that the majority of cases of valvular disease passed through labour without distress provided the myocardium was good. When failure of compensation occurred opinion was divided as to the best mode of procedure. Very little help could be obtained from the textbooks, while approval might be found for practically any method of treatment. In the early months it was very rarely necessary to interrupt pregnancy. In mitral stenosis induction of abortion was by no means free from danger. He advised induction in any case when decompensation had occurred in a previous pregnancy.

Dr. D. Lees (Edinburgh) asserted that the examination of films was of no use in the diagnosis of gonorrhoea. In suspected syphilis a provocative dose of salvarsan would frequently lead to the Wassermann reaction becoming positive, but a negative reaction was without value. He strongly objected to the phrase "venereal disease" the majority of cases occurred in those who had not contracted the disease venereally. Syphilis should be suspected in cases of aortic disease, treatment on these lines often led to improvement.

The President opposed the sterilizing of cardiac patients, especially in old standing cases. Compensation might later be established and with it the chances of a successful pregnancy being sustained. He agreed that artificial pneumothorax was a most valuable addition to the treatment of pulmonary tuberculosis.

Professor Mayo Kern in his reply stated that he had been struck by the number of times the pathologist reported the presence of fresh vegetations on the valves in cases

which terminated fatally. He thought that Mr. Paramore's suggestions in regard to hysterectomy were of great importance, and he was disposed to act along these lines in the future in cases of the type under discussion. He agreed with Dr. Macenzie that digitalis should be reserved for cases of definite decompensation.

Dr. E. Rist (Paris) explained that he had obtained his experience by an elaborate follow-up system. He was not formerly so pessimistic as at present. He thought that the physician saw patients for a more prolonged period than the obstetrician and was thus in a more favourable position to observe the bad effects of pregnancy. He did not agree that the excursions of the diaphragm were seriously impeded in pregnancy.

## THE USES AND LIMITATIONS OF ULTRA-VIOLET RADIATION IN DERMATOLOGY

### THE EVOLUTION OF ACTINOTHERAPY

BY

S. E. DORE, M.D., F.R.C.P.,  
Physician in Charge, Skin Department, St. Thomas's Hospital  
and Westminster Hospital, London

I must first express my appreciation of the honour you have done me in asking me to open this discussion although the task of replacing a distinguished foreign actinotherapist is not an easy one, and the views I shall express will no doubt differ from his.

I do not propose to bring before you details of cases which are tedious and often misleading or statistics which are notoriously fallacious but I shall endeavour to give you the impressions I have formed as the result of a considerable experience of ultra-violet light treatment in hospital and private practice extending over many years.

My first acquaintance with this work began in the year 1900, in conjunction with the late Sir Malcolm Morris, and, if you will permit me, I will quote a sentence from a paper published in the *BRITISH MEDICAL JOURNAL* of May 31st, 1902, and repeated in the preface of a little book published in 1907, stating the view we had formed of the value of phototherapy in dermatology:

Although in our opinion the results we have obtained have fully justified the employment of the treatment and in some cases no other treatment could have produced such good results we do not regard it as the only method to be used in all cases nor advocate it indiscriminately to the exclusion of other methods.

I emphasize this opinion because I think there has been a growing tendency to exaggerate the results of actinotherapy in recent years. My own view today are the same as those stated in 1902 and I expressed the same opinion two years ago at the British Medical Association meeting at Bradford and at the Royal Society of Medicine last March. I must therefore ask you to bear with me if there is a certain amount of repetition of what I said on those occasions.

The bacteriological effect of light was discovered as long ago as 1877 by Downes and Blunt, but ultra-violet light was of course first employed systematically in the treatment of disease by Niels Finsen of Copenhagen who not only advocated its use in the treatment of lupus but who chiefly devoted his attention to its use in the treatment of small pox—a method which has recently been criticized by French observers after it tried in a recent epidemic in Paris. Finsen's light treatment was first introduced into England by the late Sir Malcolm Morris in May, 1900 and I remember seeing him in the treatment of the first case of lupus at the beginning of that month. A few months later the light treatment of lupus was instituted at the London Hospital by Dr. Sequeira whose publications did so much to secure for it a permanent place in British dermatology.

\*The opening paper of a discussion on the Section of Dermatology at the Annual Meeting of the British Medical Association Edinburgh 1927. The President of the Section Dr. Cranston Low was in the chair.

Finsen used both sun and arc light, the rays being brought to a focus by means of quartz lenses, the concentrated light being cooled and the skin rendered anæmic by pressure with a quartz vessel containing circulating water. The fact that the original type of lamp is still employed at the London Hospital and other institutions is sufficient evidence that the principles laid down by Finsen—namely, the necessity of concentrating the light and compressing the tissues to allow penetration of the ultra-violet rays—still hold good, although they seem to have been forgotten by a good many workers of the present day.

The original Finsen lamp was a cumbersome and expensive piece of apparatus devised for the treatment of four patients, and this was improved upon by Reyn, who used a focusing tube embodying the same principles and adapted for the treatment of a single patient. With both these lamps, however, the exposures were so long, and the area treated at each application so small, that the results obtained in extensive cases were slow and comparatively ineffective. Attempts were then made to obtain penetration and increase the size of the area exposed by bringing the source of light close to the skin, burning being prevented by the interposition of a quartz lens containing circulating water, which was placed in the path of the diverging rays and brought into contact with the skin. This was the principle of the apparatus devised by Loret and Genoud, which was modified for use at the London Hospital, being known as "the London Hospital lamp," and was the forerunner of the Kromayer lamp, in which the U-shaped mercury vapour burner replaced the carbon arc.

An attempt was also made to increase the proportion of ultra-violet rays and decrease the time-of-application by using iron electrodes, circulating water or ice being employed to intercept the heat rays. The action of these lamps, however, proved too superficial to affect the deep infiltration of lupus, and the results were less satisfactory than those obtained by the more penetrating concentrated rays of the Finsen lamp. Another development was that of the Simpson arc in which wolfram electrodes were employed. Dr Sequerra demonstrated the superficial action of this lamp and the failure of the rays to penetrate even a thin sheet of paper, a disadvantage which still holds good for the tungsten and mercury vapour lamps used at the present day.

I have dealt at some length with the evolution of these different types of lamps, because we are still faced with the difficulty that the mercury vapour and tungsten lamps lack penetrating power, whereas the available arc treated by concentrated carbon arc rays is too small to give entirely satisfactory results. For those of us who have charge of large dermatological clinics, and have the disheartening experience of seeing numerous cases of facial lupus every week, it is an undoubted advantage to have at our disposal a conservative method which can be repeated almost indefinitely from week to week, with much mental comfort and little physical discomfort to the patient, who is thereby kept under constant supervision, and quite rightly encouraged to persevere with the treatment in the hope of eventual cure. But, speaking from my own experience, I doubt if many extensive cases of lupus are cured by unaided light treatment. With surgical measures and such applications as red nitrate of mercury, pyrogallol acid—which is, I believe, extensively used in Denmark—and other selective caustics, we are able to accomplish in a short time and with little expense, although with more pain and scarring, what it would take months of light treatment to achieve.

Lupus rarely tends to get well spontaneously, but in alopecia areata, another condition for which light treatment is widely advocated, there is a tendency to spontaneous recovery which makes it more difficult to assess the value of treatment. There is no doubt that ultra-violet irradiations are an excellent stimulant of hair growth, I have seen growth of hair occur on a bald scalp in circles corresponding to the area covered by the pressure glass of the Finsen lamp, but the results with the mercury vapour and tungsten lamps are less convincing. In this disease, as in lupus it seems that the result depends upon the intensity of the inflammatory reaction, in other words, the actinic rays act as a counter-irritant in a similar manner

to the various stimulating preparations which are commonly used when light treatment is not available.

In psoriasis there is considerable difference of opinion regarding the response to actinotherapy. I have seen extensive eruptions clear up under light baths and relapse during a continuance of the treatment, and the majority of cases in my experience have shown little permanent improvement. Possibly patients treated with carbon arc lamps are benefited by the heat rays and the sweating produced, although I have noticed that in cases treated by radiant heat the psoriasis patches sweat with difficulty. It seems probable that if the applications are pushed to the point of causing erythema and desquamation, in which the psoriasis shrives, better results are likely to be obtained than those in which little inflammatory reaction is produced. On the whole I agree with Dr Roxburgh, who has written one of the most unbiased papers I have read on the subject, that "in most cases an equal degree of benefit can be achieved more quickly, though less pleasantly, by the use of chrysarobin."

In tinea vulgaris the suppuration is to a certain extent controlled, but improvement is chiefly due to exfoliation of the skin, and the results of actinotherapy are not much better in my experience than those obtained by keratolytic preparations, and much inferior to those produced by x-rays.

Cases of impetigo and staphylococcal infections which fail to yield to the ordinary antiseptic applications are benefited by light, and the same may be said of chronic septic and tuberculous ulcers, and some neurosphyrial conditions. The sphere of light treatment has been greatly extended during recent years, and it would be impossible to refer to all the pathological conditions for which it has been advocated, nor is it necessary to discuss the more general aspects of actinotherapy, such as the results obtained in rickets, or the well known work of Rollier and Gamm on surgical and other varieties of tuberculosis. What concerns us more particularly as dermatologists is the combined local and general use of light therapy. This was first advocated for lupus by Reyn, of the Finsen Institute, in 1918, who stated that the percentage of cures obtained by this method was increased from 60 to 60 per cent. Heiberg and With gave the percentage as 90, and stated that light baths alone could cure lupus without any local treatment, the same results having been previously claimed by Stindberg and Heiberg for intranasal lupus. Dr Sequerra confirmed the value of the combined method, which he introduced at the London Hospital in 1922. I have had many cases of lupus treated in this manner, and in at least one extensive case of lupus of the face remarkable improvement followed light baths alone, while others have not improved when both local and general treatment have been adopted.

Time does not permit me to discuss the biological properties of ultra-violet irradiations, but it seems probable that their action is mainly distinctive, the defensive properties of the tissues being stimulated by the products of the damaged cells. That light can have pathological effects on the skin is well known to dermatologists, as exemplified in such conditions as xeroderma pigmentosum, hydrotic vesicle, solar dermatitis, etc., and it is recognized that harmful results may occur from excessive therapeutic exposures, or from the injudicious treatment of acute and febrile cases. On the other hand, there is abundant evidence of improvement in the nutrition of children and adults as the result of actinotherapy, although the exact mechanism of its production is not clear. In rickets, in which the mercury vapour lamp appears to give the best results, it is thought that the effect is due to the activation of the cholesterol of the skin, whereas in surgical and other forms of tuberculosis carbon arc light, with its greater preponderance of luminous and heat rays, is the method of choice where sunlight is not available, and heat and flesh are the probable factors in the increase of haemoglobin and leucocytes, and in the bactericidal power of the blood.

It seems probable that the well known stimulating effect produced on fully clad operators working in close proximity to ultra-violet rays may be due in part to inhibition of the ionized air. It is well known that inhibition of the

vapour given off by tungsten arcs has been employed successfully in asthma and other bronchial conditions in children. The fact that suggestion may also play a part in the results is often overlooked and, without attributing too much importance to this factor, it is possible that the psychological effect may have no small influence even in infants.

The luminous and heat rays must also be taken into account. When the comparatively small number of ultra-violet radiations—none below 2,970 Angstrom units—which penetrate the atmosphere is considered it seems doubtful if the health of the community can be dependent to any large degree upon the short wave radiations and the value of such improvised measures as the provision of ultra-violet-passing glass in smoke-laden cities seems problematical, and in country districts superfluous.

It has been shown by Leonard Hill that the basal metabolism rate is not raised by actinic light unless accompanied by the cooling power of air. Hess gives charts showing the amount of sunlight in five of the great cities of the world, New York having twice as much as London, and more than Berlin, Paris, and Stockholm, but he forgets to mention Edinburgh. In this city, where cooling winds predominate and perhaps sunlight is not at its maximum, you will probably agree that the hardy northerner takes precedence in health and endurance of the softer, sunbaked, ultra-violet lighted inhabitant of the south.

In conclusion may I say that if I have taken, as some may think, an unnecessarily pessimistic view of the value of actinic light in therapeutics, I am far from wishing to depreciate a measure which aims at the relief of disease and the improvement of the public health, and I hope this discussion will not only help to place actinotherapy on the proper scientific basis it deserves but will lead also to further progress in the knowledge of its effects and still better results from treatment.

# DISCUSSION

Dr F GARDNER (Edinburgh) thought that too much stress could not be laid upon the psychic effect of a new remedy such as this, administered in the semi-theatrical manner of all electrical treatments. The accurate and scientific dosage and the limitations of the new therapy could not yet be stated. Rickets was undoubtedly greatly benefited, but in other conditions the value of light was less certain. It was necessary to consider not only the various sources and wave lengths but also superficial and deep effects and the compression or absence of compression of the tissues. It was still doubtful whether the ultra-violet rays could or could not penetrate to a greater or lesser degree the epidermal horny layer and the blood and to what extent they were bactericidal. In tuberculosis of the skin the benefit, especially of a cosmetic character, was very noticeable but there were occasional failures, most often when pulmonary affection was also present. In one case he had found by means of a-ray examination enlarged bronchial glands, in another the fumes of the lamp produced bronchitis. The fungating and ulcerative types responded better than the fibrous type. From January, 1924 to June 1927, 171 patients had been treated at the Royal Infirmary with the carbon arc. 27 had been discharged provisionally cured, 65 as improved while 76 were still under treatment. In addition to using the arc light it had been their custom to treat stubborn areas with trichloroacetic acid and other caustics. Better, especially, cosmetically, better results and a higher percentage of cures were obtained by light treatment than by any other method. Tuberculous, such as Bazin's disease and allied conditions, healed remarkably well, and many cases of lupus or the matous also did well. Skin diseases associated with general debility were benefited—as for example long-standing prurigo in debilitated children or the other hand prurigo in adults was aggravated. Extensive pitular cases of acne vulgaris affecting the back and chest were much improved. The systemic treatment of bad scrofula in debilitated subjects was useful. He warned against the dangers of unskilful use of the mercury vapour lamp and thought that it was very unsatisfactory in psoriasis. In alopecia areata he had had good results,

but not equal to those expected by Nagel Schmidt. In ulcers of the leg although it benefited those of the Bazin type it was useless for varicose and chronic ulcers. He concluded that the effects of the treatment were systemic and should be used where there was some general systemic disturbance, they stimulated certain areas and might be used to reduce pustulation.

Dr W J O'DONOVAN (London) described the origin of the light department at the London Hospital which was opened on May 1st, 1900, with the lamps from Copal-hagen given by Queen Alexandra since then 2,800 cases of lupus had been treated. He emphasized the necessity of prolonged and uninterrupted treatment and the equally continuous supervision of the patient in these conditions were fulfilled the prospect of curing the cases was good. He thought that the only incurable type was that in which there was lymphatic obstruction of the area affected usually the face, with this exception and with the help of proper supervision he could claim 90 per cent cures. The introduction of light bath treatment at the London Hospital was second only in importance to the original application ofinsen light to the treatment of lupus. Some cases were healed by light baths alone, these were subsequently combined with local treatment. The light baths had perhaps been particularly valuable in dealing with lupus of the mucous membranes which before 1922 had to be treated by surgical methods alone, it was often impossible to reach by these means the whole of the diseased area. A few cases always relapsed a few months after the suspension of treatment, for these a prophylactic course of light baths every year was advised. In the whole series there had been three deaths from meningitis. The only other bad effect which had been noticed was the occasional occurrence of tropical fatigue during general light treatment. He stated that there was no evidence whatever that carcinoma ever developed on the healthy scars left afterinsen treatment, although he was very familiar with carcinoma engrafted on lupus itself and on the scars left by x-ray treatment. Light therapy in psoriasis was of very occasional benefit in acne very doubtful. He had known acne develop during retinal light treatment. Cases of prurigo in general improved and multiple subcutaneous abscesses in infants did very well indeed with it but exfoliative dermatitis was sometimes produced. It was also most valuable in the septic complications of compound fractures in securing the separation of sequestra and the healing of troublesome sinuses.

Dr J GOODWIN TOMKINS (Glasgow) said that his first acquaintance with heliotherapy dated from the Paris congress on tuberculosis in 1905 while his first case was that of a lady who began heliotherapy under his instruction for lupus in Egypt in 1908 and did very well indeed. Since then he had had other patients treated on the arc lines at Darga in the Apennines at Viareggio and at Leysin. The value of heliotherapy was indubitable and the various ultra-violet light lamps were very efficient substitutes for sunlight though not for the invigorating atmospheric conditions of high altitude. Most of the cases for which he prescribed the artificial sun in bath were tuberculous. A noteworthy feature of these patients was their cheerfulness due no doubt to their progress toward cure and to the absence of pain and discomfort in the treatment. He thought it was early to form a final judgement as to its exact limitations but it only removed some of the loathsome features of an extensive ulcerative tuberculous condition and was useful in controlling it. It would still be one of the most useful therapeutic agents that the present century had produced.

Dr H MacCORMAK (London) agreed with Dr Dore that many extravagant claims had been made for the treatment by ultra-violet rays but admitted that it was a very valuable method of treatment, especially in lupus vulgaris as shown by the high proportion of cures obtained by Peven and others. His best results had been obtained in lupus but he had also seen the rapid of prurigo completely fade. The effect of ultra-violet light was however, very variable in psoriasis and he remembered one case in which the disease extended rapidly all over the

body, except over an area covered by short trunks worn by the patient while undergoing treatment. He had also found the light bath a valuable adjunct in cases of trabs with debility when, owing to the patient's general condition, intensive antisyphilitic treatment had ceased to be efficacious, or had actually become harmful.

Dr GILCHRIST (Baltimore, U.S.A.) described a new method of measuring the dosage of ultra-violet light by means of lithopane. He referred to attempts in the United States to ascertain whether it might be possible to desensitize individuals vulnerable to light by means of small doses, just as desensitization to proteins could be produced. He also mentioned the discovery of a new range of rays between the ultra-violet zone and x rays, which were called "border" rays. Investigations in haematomorphyrinuria had revealed that the cause of death was the depression of blood pressure and dilatation of vessels. In lupus he had found diathermy the best method of treatment. He was optimistic about the treatment of psoriasis.

Sir NORMAN WALKER (Edinburgh) indulged in reminiscences. He said that the London Hospital lamp employed thirty years ago in Edinburgh did not then apparently give good results, but ultimately the patients did well. He asked whether strong lamps acting for a short time had as good an effect as weaker lamps acting for a longer time. His great recipe for the successful treatment of lupus was perseverance. Another indispensable factor was early and accurate diagnosis, which nowadays was far better than it used to be. He expressed optimistic views as to the prognosis and treatment of psoriasis.

Dr W MITCHELL (Bradford) preferred diathermy to any other treatment for lupus, owing to the excellent scars which were left. He also used it in the treatment of cancer of the tongue and tonsils. He mentioned an interesting case of a girl who developed menorrhagia after every exposure to ultra-violet light.

Dr A C ROXBOROUGH (London) referred to the employment of ultra-violet light in the diagnosis of ringworm of the scalp. Infected hairs examined in a dark room by ultra-violet light passed through a piece of Wood's glass shone with a brilliant green fluorescence. They had been using this method at St Bartholomew's Hospital for the past six months, both for detecting very early infections and for deciding whether cure had been attained after perhaps rather incomplete epilation with either thallium or x rays. He had found ultra-violet light very useful in tuberculosis of the skin as an adjunct to local treatment, but in one or two cases he had seen an unsuspected tuberculosis of the lungs light up. Other conditions which did well were multiple boils, superficial sepsis, and, in a few cases only, chronic dermatitis and eczema, the latter were very easily irritated by light, and treatment should commence with extremely small doses. He had found local applications by mercury vapour or the tungsten arc most useful in healing ulcers and sluggish wounds—as, for example, after mastoid operations—also in various forms of alopecia and impetigo contagiosa, but not in cases of premature baldness. In psoriasis progress was slow and uncertain. Acne vulgaris and rosacea sometimes benefited, but on the whole did better with x rays. Telangiectases following excessive x-ray treatment could be materially reduced by local treatment with the mercury vapour lamp.

Dr HOWITT (London) said that the action of the sympathetic nervous system was an important factor in ultra-violet light therapy. He also emphasized the necessity of perseverance if good results were to be expected.

Dr KERR RUSSELL (Newcastle-on-Tyne) said that there was no difference between the results obtained at Dr Rollier's clinic at Leysin, where natural ultra-violet light radiations were used, and those obtained at the Finsen Institute, Copenhagen, where carbon arcs were solely used. Those who thought sunlight superior to artificially produced radiation should ask themselves, How could sunlight be used for the treatment of a case, say, of port wine stain? For these cases a lamp of the Kromayer type was essential. He deprecated the allusions to the psychical effects of the treatment.

Dr CHRISTINA BIRROWMAN (Newcastle-on-Tyne) said that ultra-violet light had a very wide application in the treatment of burns, the relief of pain, the prevention and cure of sepsis, the healing of fairly extensive areas without grafting and with little evidence of cicatrization, and the general appearance of well-being of the patient were important features. On the Continent the ultra-violet rays had been successfully applied through cellophane dressings, use of this artificial silk fabric avoided frequent change of dressings and allowed very easy application of ultra-violet rays. Recent infections of tinea capitis yielded to the action of the rays, she had cured a baby aged 2 months with two applications. In more chronic cases, although some of the recently infected areas disappeared, examination under Wood's glass showed that infection was still present.

The PRESIDENT emphasized the frequency of carcinoma following x-ray treatment of lupus, and sounded a note of warning as to the possible risk of a similar danger after the use of ultra-violet rays. An attempt should be made to find out the general principles which underlay the treatment. He suggested that in lupus there was always a positive skin reaction, this indicated that in lupus the antibody to tubercle was anchored in the skin. When the skin was exposed to ultra-violet rays an erythema was produced that caused congestion of the skin and absorption of those antibodies which were carried by the circulation to the tuberculous lesions. In all infective diseases where a positive skin reaction was present the ultra-violet ray treatment was likely to do good.

Dr DONE, in reply, agreed that in lupus vulgaris other methods, such as diathermy and the use of salicylic acid, should be combined with light treatment. Continuous daily applications were required, but excessive exposure might have the opposite effect to that desired. Edinborough had recently stated that there was a period of immunity, lasting fourteen days, following the exposure of a given area to ultra-violet light, and suggested that better results would be obtained if that interval of time were allowed to elapse between the exposures. In the case of children it had been shown that too long or too frequent exposures had a detrimental action. He had tried the treatment of ringworm by ultra-violet light without success. Although it was possible that a superficial infection in an infant might respond (as it would to antiseptic applications), ordinary ringworm of the scalp in children could not be healed successfully in this manner.

## THE TREATMENT OF LUPUS ERYTHEMATOSUS BY KRYSOLGAN\*

BY

HENRY C G SEMON, M.D., M.R.C.P.,  
Physician to the Skin Departments, Royal Northern and  
Hampstead General Hospitals

The etiology of lupus erythematosus is still a matter of conjecture, and no decisive facts have emerged since Dr A M H Gray summarized the position in a paper read before the British Association of Dermatology and Syphilology at Manchester in 1925. Two theories of causation are favoured—the tuberculous, mainly in France and Germany, and the streptococcal, which finds its chief adherents in this country.

The results of the gold therapy of the disease, which were not considered at Manchester, seem to me, so far as they go, to support the tuberculous theory, and I am further inclined to that assumption by a consideration of the facts elicited by Jorgen Schaumann from three post-mortem examinations of patients who died as a result of, or in the course of, the disease. This author's brilliant work on certain sarcoids, which he has renamed the benign lymphogranulomata, is well known, and entitles his present pronouncement in the case of lupus erythematosus to more than a cursory perusal. In these three fatal cases Schaumann demonstrated a "special granulomatous process in the lymphatic system, combined in the third case with classical tuberculous lesions, in which necrotic phenomena were conspicuous."

\* Read in the Section of Dermatology at the Annual Meeting of the British Medical Association, Edinburgh, 1927.

I need not here detail the exact cellular structure of the tissue to which he refers, it is only necessary to explain that "disseminated in that tissue there were to be seen many small tubercle-like foci mostly well defined and often surrounded by a zone of lymphoid cells." Inoculations from these foci into guinea-pigs were negative as regards tuberculosis, but several weeks later the animals mostly succumbed, either to pneumonia or to a form of narasmus in exactly the same way had occurred after similar injection experiments with specimens from cases of sarcoid disease (benign lymphogranulomatosis) the tuberculous nature of which is now generally accepted as proven. The author further points out that coccal infections are not infrequently a terminal event both in lupus erythematosus and other "lymph system" diseases, and to me it seems likely that there is in lupus erythematosus an acquired susceptibility in this respect, which may account for the undoubted frequency of focal septal tonsils, intra-frontal sinus, and even teeth in many of the cases and may come to be regarded eventually rather as a complication than as an etiological factor in the pathology of the disease. Some further support of Schramm's belief is afforded by the "leucocytic formula" of lupus erythematosus, which closely resembles that usually found in the benign tuberculous infections but the most cogent argument, and one which it is in the capacity of all of us to examine and critique, is that based on the previous history, personal and family, and the results of the von Pirquet or complement fixation tests in the individual patient. I am persuaded that in the words of Schramm, "the observation cliniques montrent trop souvent l'apparition du lupus erythematosus chez des anciens crofulo-tuberculeux pour que nous puissions écarter toute idée de rapport de cause à effet." In the series, short though it is, of the krisolgan-treated cases I am about to report there was in the majority a history either of pulmonary tuberculosis or pleurisy, and the results of the von Pirquet test in the remainder were at least suggestive of a tuberculous diathesis.

The gold treatment of tuberculous manifestations of all kinds has been on trial for the past two years. There is no doubt of the value of the procedure in certain types and stages of this protean disease and krisolgan is an attempt by the well known firm of Schering to produce a relatively non-toxic salt of the metal. It has the formula  $C_6H_5NH_4S_4O_6Na$ , and is a member of the group of gold thio-phosphates. It is administered solely by intravenous injection, and should be dissolved in the returning ampoule in one or two cubic centimetres of sterile distilled water. The makers state that in non-tuberculous cases no effect is observable even after doses of 7.5 grains. The highest single dose advised in the treatment of lupus erythematosus is 15 grains. I have not exceeded 125 grains for the drug is cumulative, and when a week later, that dose was followed by one of 0.75 grain there ensued (Case 1) symptoms of prostration and cardiac weakness although no pain or harm resulted.

The question of dosage is the most disputed point in connexion with the drug and while the pioneers are still in doubt it is perhaps wise to err on the side of caution even at the risk of therapeutic failure. My practice nowadays is to commence with a dose of 0.015 grain a week, then 0.15 grain is given, and then 0.375 grain. If no toxic symptoms supervene the next dose would be 0.75 grain but if improvement has manifested itself on the previous dose I should prefer to repeat it, and continue to do so weekly while its effects were favourable. Every case selected for the treatment must be tested for albuminuria which, if caused by renal tuberculosis, is a direct contra-indication. One of the only two deaths recorded in the literature was due to anuria resulting from a severe renal reaction to the drug.

There are other toxic symptoms beside albuminuria but none of them so serious—for example, stomatitis and dermatitis which may resemble that due to novarsenobismuth or more anaphylactic in type and resembling urticaria or erythema multiforme. I saw the latter type in one of my series (Case 1). Fleeting pruritis in facial spaces are very common especially in the neck and round the face joints and it may be mentioned here that I found an intravenous

injection of 0.6 gram of sodium thio-sulphate exceedingly quick and efficient in their removal in one or two cases. Depression, fatigue and melancholic tendencies were rather prominent in three cases. Lebril reaction on at least in the two cases observed as in patient at the Royal Northern Hospital, were conspicuously absent. Facial reaction indicated subjectively as irritation and visible as an increase in erythema, I have come to regard as of favourable prognostic import, though its absence need not discourage further treatment (Case 11).

Since the first case in which I made trial of it exhibited some interesting and characteristic features I report it in rather more detail than I shall give to the others.

#### CASE 1

A married woman aged 59 came home from China in 1925 with suspected pulmonary tuberculosis which was not confirmed in London. In 1925 she had two or three attacks of pleurisy. Eruptions of the face occurred in 1918 and in 1925 there appeared crusting in the nose, headache and a tendency to eczema behind the ear with loss of hair. In 1924 a rash appeared on the scalp margin forehead and in front of the ears. On November 26th 1925 the patient had a scalp superficial type of lupus erythematosus of the pre and postauricular region, the forehead and scalp margin. Very little cicatricial tendency was observable. She was a rather feeble subject with cardiac asthenia, a poor colour, some dullness at the right base (C1 pleurisy) and some crusting in the nasal cavity. On January 25th 1926 she had an operation for right auricular valve made from a streptococcus recovered from pus. From February to April 1926 twelve injections of 1 cc. of gold vaccine were given without any benefit to the lupus. On March 28th the facial lesions were as above and there were also scalp macules of a bright reddish tint on the backs of the hands and on the neck.

Krisolgan injections were given as follows: on August 8th 0.015 grain on August 25th 0.015 grain on September 1st 0.375 grain on September 8th 0.75 grain and on September 15th 1.125 grain. There were joint pains, followed by diarrhoea, slight pyrexia and some hyperaemia of the face. No pyrexia was observed at any other time. An injection of 0.75 grain on September 22nd was followed the next day by symptoms suggesting cardiac instability and weakness for which rest was enjoined. On October 6th the patient felt better. All the lesions were paler. On October 23rd 0.75 grain was given and on November 3rd local hyperaemia was pronounced. Additionally there were a few rose-coloured and yellowish brown medallion lesions at the waist line (von Noorden's anaphylactoid rash). On November 24th all the lupus lesions had involuted there was delicate crusting and over the right preauricular region a light brownish purple discoloration extended to local direct action and deposit of a gold salt. In March 1927 the husband reported that she had no recurred and that the general health was in every respect greatly improved. He added that he would immediately acquaint me with any local or general manifestations that might take place in the future.

In this case we cannot I think ignore the very striking history which is suggestive both from the tuberculous and streptococcal points of view. Apart from the suggestion of pulmonary tuberculosis there were live attacks of pleurisy while erysipelas aortic and other evidence of a susceptibility to streptococcal infections may have had some etiological influence at a later date. Her general condition was poor at the commencement of the treatment and appeared to be aggravated by the anaphylactoid streptococcal vaccine from the nasal infection. The spread of the eruption to the backs of the hands at this period suggests that the streptococcus was the actual envenoming agent. It is a fact that the lupus erythematosus was completely eradicated in this case but not before the patient had some rather the more or less severe anaphylactic reaction set up by the krisolgan injection. That these effects are a cure of the local condition is a great gain but even more so was the effect on the general health. The symptoms of fatigue and mental lassitude were a feature of the disease and the inability for sustained effort of an kind were greatly benefited and in her husband's words "he is now capable of doing much more than formerly. He is stronger and energy tires him easily and in the past he astonished me by her capacity for sustained effort. He has lost weight which had given her so much trouble. I now much stronger—very little pain and palpitation, ordinary etc. now."

To me it would seem that in addition to the visible effects of the treatment on the lupus lesions there must have been some subtle action of the drug on some deep (possibly glandular) foci of an active type in the chest or abdomen.

## CASE II

A single woman, aged 67, had had scattered lupus erythematosus of the face, neck, tip of nose, and right ear for seventeen years. There was no history of tuberculosis or pleurisy either in herself or family. Various treatments, including carbon dioxide snow, autogenous vaccines from enucleated tonsils (1919) for a period of six months in a London hospital, and local applications, failed to do more than afford temporary relief.

On admission to the Royal Northern Hospital on January 13th, 1927, the von Pirquet reaction was strongly positive and persistent. She was of a stout pale phlegmatic type, and breathlessness ensued on slight exertion. Cardiac enlargement, and weakness of the cardiac musculature, with a pronounced presystolic bruit, were obvious features in the case.

Between January 13th and February 23rd, 1927, five doses of krysolgan were administered at weekly intervals, rising from 0.015 to 0.75 gram—in all only 2.04 grams. On March 9th all the lesions had completely involuted leaving delicate, pale, and almost invisible atrophic patches in their original sites.

This patient had always been subject to vague rheumatic pains around the joints. They were greatly aggravated, especially in the neck muscles and around the knees, by the injections. The intravenous administration of sodium thiosulphate (0.6 gram) was very effective in relieving

## CASE III

A married woman, aged 42, had had lupus erythematosus of the face, nose, tip of right ear, and scalp for twenty years. The lesions were scaly, of chronic erythematous and very irritable type. Scarring was very slight. She had had pleurisy seven years previously. Auscultation and x-rays revealed nothing abnormal, the von Pirquet reaction was slightly positive. She received many local treatments—carbon dioxide snow, Kromayer lamp, phenol, lactic injections, etc.—without much benefit.

She began krysolgan treatment, as an out-patient of the Royal Northern Hospital, on February 2nd, 1927. Between this date and March 30th four injections of krysolgan were given, rising from 0.015 to 0.75 gram—1.515 grams in all.

On April 27th the facial lesions had involuted, and the scalp lesion, which had shown marked local irritability throughout the course, was pale and no longer tender to the touch.

When seen on June 30th the facial lesions had not recurred, and the patient looked and felt extremely well. She had put on 2 st in weight since she first began the krysolgan treatment. The scalp lesions had not benefited at all from the treatment, and a further course, together with iodine (Ficuch Codex) by the mouth, has been decided upon.

## CASE IV

A married woman with two children had had a typical butterfly distribution of subcutaneous type for two years. There was no tuberculous history. A sister also has lupus erythematosus and attended with the patient on one occasion for diagnosis. In December, 1926, an abdominal mass in the ilio-cæcal region was thought by Dr. Bruce-Williamson to be due to tuberculous glands. The von Pirquet reaction was very violent, and accompanied by fever and prostration for three days. Local reactions developed in the lupus lesions a week later, and subsequent pricking was noted at a later date. The improvement was only temporary.

She was admitted as an in-patient on March 20th, 1927. Examination for focal sepsis in the teeth, sinuses, and tonsils was negative. Between March 23rd and May 19th six injections of krysolgan were given without any constitutional effects, dosage 0.015 to 0.375 gram at weekly intervals.

On May 19th there was great improvement in the general health, with gain in weight and decrease of the ilio-cæcal mass. The lupus lesions, which had reacted throughout with increase of irritation, were still present on the cheeks and bridge of the nose but were reduced to linear dimensions; the central portions having cleared up without any tendency to atrophy or scarring. She is continuing the treatment with injections as an out-patient.

## CASE V

A married woman, aged 27, first seen as a private patient on December 12th, 1925, had had lupus erythematosus of the cheeks and temporal regions for four and three-quarter years. The tonsils had been removed at another dermatologist's suggestion, also several teeth, without benefit to the eruption. Vaccines from the above sources proved ineffective. At her confinement all the lesions involuted, but recurred a few months later.

During treatment applied by me between March 19th and November 29th, 1926, six injections of silver sal. were given. A marked improvement. Other treatments included application of carbon dioxide and Unna's microbrenner, guanine and tincture of iodine (Ficuch Codex) by the mouth without ascertainable results. Krysolgan was begun on November 29th, 1926, and doses of 0.375 gram to 1 gram were given at intervals of not less than a week. Up to May 22nd, 1927, 5½ grams had been administered. There is now very great improvement, three of the lesions—those in the temporal regions and on one cheek—have completely involuted, the former with a slightly bluish tinge (gold deposit), there is a slight tendency of a very small lesion to persist on the right cheek.

## CASE VI

A man, aged 46 (a private patient) twenty years ago was treated for pulmonary tuberculosis in a sanatorium in California. He first consulted me on June 25th, 1925. Fifteen years ago he first noticed a warty and striking condition of the nose in the region of the left nostril and similar small patches behind both ears over the mastoid processes. When first seen by me he had typical but exceedingly chronic lupus erythematosus which had led to some considerable atrophic deformity in the left naso labial

angle. Previous treatment by radium in New York was doubtless responsible for the few telangiectases present. There was scarring of the patches over the mastoid processes. The lupus was slowly progressing with a raised scaly edge on the left upper lip. The internal aspect of the left chlorea was slightly affected.

On June 25th, 1925, carbon dioxide snow was applied to the advancing edges, two applications were sufficient, and the patient returned to America. When seen again, on March 21st, 1927, the condition was very much the same as when he was treated two years previously.

A course of krysolgan treatment was agreed to and between March 21st and May 13th six doses, rising from 0.075 to 0.75 gram, were injected—2.3325 grams in all. On May 13th, 1927, there was very definite flattening of the raised hyperæmic edge, and complete cessation of the tendency to scalo. A complete cure could not, however, be claimed. Throughout the course the patient complained of more or less severe pain in the back of the neck, and a feeling of fatigue and mental depression. I think that in this case the marked cicatricial effects of the disease and the consequent damage to the local circulation militated against a free access of the drug to the affected area.

## CASE VII

This patient, a man aged 30 (a severe case of neurasthenia due to shell shock), had been under treatment by various physicians at the Ministry of Pensions and the Hampstead General Hospital since 1915. On July 20th, 1925, the lupus erythematosus was limited to the scalp, where there was an extensive cicatricial hyperæmic and denuded patch including the vertex, frontal, and some of the parietal areas.

The nervous state of the patient prohibited any drastic local applications, and treatment was confined to soothing lotions and the internal administration of tincture of iodine (Ficuch Codex), which was continued without any effect on the local condition but with benefit to the general health, until December, 1926. There was no history of any tuberculous condition in the patient or his family. The von Pirquet test was weakly positive.

From January 24th to April 4th, 1927, krysolgan treatment was given in doses rising from 0.015 to 0.75 gram weekly, the total administered being 3.3 grams. The result showed no appreciable objective effect on the lesions at the conclusion of the course, although there appeared to be some increase of the hyperæmia, and the patient complained of aggravation of the irritation after two of the larger doses.

Note—It is, of course, open to question whether the diagnosis of lupus erythematosus was justified. Syphilis was excluded by a Wassermann test.

## CASE VIII

A man, aged 33, first seen on August 6th, 1926, had a nine years' history of a red scaly patch limited to the bridge of the nose, there was a slight cicatricial tendency. He was subject to frequent sore throats and colds. There was no suspicion of tuberculous in the patient or his family. Carbon dioxide snow applications effected some improvement, but on February 28th, 1927, there were four fresh areas or relapses in the previously affected area. From March 21st to May 23rd, 1927, four injections of krysolgan—1.88 grams in all—effected a striking improvement in the local lesions. There was brownish discoloration in the central part of the area, similar to that described in Cases I and V.

This case cannot be claimed as a cure, and is still under observation.

## CASE IX

A man, aged 41, an out-patient at the Royal Northern Hospital, had typical butterfly localization of the chronic scaly indurated type of lupus erythematosus on the cheeks, lower third of the nose, and the lobes of both ears. It was first noticed about a year ago. There was no history of pleurisy, glandular trouble, or tuberculous affections in his family. The von Pirquet test was feebly positive. Dental and throat reports were negative. No treatment of any kind had hitherto been given or applied for.

He was given injections of krysolgan in doses as follows: On June 8th, 1927, 0.015 gram, June 15th, 0.375 gram, June 22nd, 0.75 gram, June 29th, 0.75 gram. On this date some local improvement was noted, the lesions were decidedly paler and less scaly. On July 6th he received 0.375 gram, he complained of depression and feeling dazed since the last dose, the urine was normal, there had been no febrile reaction hitherto. On July 13th he was again given 0.375 gram—making a total received by the patient of 2.640 grams. He now showed very definite improvement, both objectively and subjectively, in the feeling of irritation. The nose had completely lost its tendency to scaly exfoliation, and there was less erythema, and the infiltration had almost involuted. Similar changes, rather less marked, were noted in the remaining lesions.

This is the most typical case of the fully developed disease in my series. The patient is greatly encouraged by the results so far obtained, which are certainly striking. In this case I am supplementing the krysolgan with oral administration of tincture of iodine (Ficuch Codex) 5 to 30 minims three daily.

It is obvious that with so small a series no very definite conclusions can be emphasized, but there are a few points of interest. Of the nine cases reported, two are assumed to be well, and both were demonstrated as cures at the Dermatological Section of the Royal Society of Medicine. Only four months have elapsed since the cases were exhibited, and relapses may yet occur. In one case the

facial lesions cleared up, but the scalp lesions were not influenced to any extent. Five cases were greatly improved and one, a case limited to the scalp, remained uninfluenced.

I am therefore able to record 22 per cent cures, 66 per cent improved, and 11 per cent uninfluenced. These results do not compare favourably with those reported in Germany by Martenstein in 1922 (66.5 per cent cures, 14.5 per cent improved), Ullmann, Fried, and other workers. Schamberg has recently published success up to nearly 50 per cent in twenty-five cases treated with sodium and gold thiosulphate (sanoerxsin). It is quite possible that my series differs both in their selection as suitable cases and in the relatively small amounts of the drug administered.

The striking preponderance of either a tuberculous history (three cases) or a strongly positive von Pirquet reaction (four cases) in a series of nine, one of which was not examined from this point of view, lends considerable support to the theory advanced by Schramm and those who favour the tuberculous etiology of lupus erythematosus.

In conclusion I desire to state that in my opinion kysolgan has established itself as a most valuable remedy in the treatment of lupus erythematosus, and that if it really has a specific action on tuberculous foci its effect lends further support to the theory of a tuberculous origin of the disease.

## THE TREATMENT OF RINGWORM OF THE SCALP BY THALLIUM DEPILATION

BY

G B DOWLING M.D.

Dermatologist, West London Hospital

Depilation of the whole scalp is generally admitted to be an absolute necessity in all cases of ringworm of the scalp, with the single exception of kerion, which does not require this treatment.

While x-ray depilation has been the customary method of treatment for about thirty years, and on the whole a very successful method, there are certain objections to it which are obvious and well recognized.

1. A x-ray can only be employed with safety by those who are highly skilled and constantly employed at the work, for the dose must be very exact. A small margin of error on either side will result either in failure to produce complete defluvium or, on the other hand, in some degree of permanent alopecia. The possibility of the latter accident is the most serious objection to the method.

2. X-ray depilation is impracticable, or at any rate very difficult, for children of 3 years of age and under, for the reason that they cannot as a rule be made to keep still for the time necessary for a depilatory dose. Dr J. M. H. MacLeod has overcome this difficulty by means of a special apparatus which he has invented, but it is a method which at present at any rate cannot be applied universally.

3. A very unpleasant though temporary inflammatory reaction of the scalp occasionally follows irradiation, while any inflammation already present is invariably aggravated, so that cases of inflamed ringworm (I do not refer to kerion) are not suitable for immediate x-ray depilation.

Any reliable alternative method of producing defluvium would therefore undoubtedly be a welcome addition to the already existent methods of attacking the disease.

The depilatory action of thallium acetate has been well known for many years, and about thirty years ago Sibouraud attempted to use the drug for the treatment of ringworm. He came to the conclusion, however, that the method was unsafe, in all probability the doses he gave were too large. At all events it was given up. After Sibouraud's therapeutic failures no attempt to make use of thallium for its depilatory action appears to have been made until quite recently, and it is due entirely to the experimental researches of A. Buschke that the method has at last attained a degree of practical usefulness.

The advantages of making use of this property of

thallium are obvious, but a dose had to be found that would be effective and at the same time non-toxic. So about twenty years after Sibouraud had abandoned his therapeutic trials in this direction, A. Buschke, at first alone and afterwards in collaboration with L. Peller and others, took the experimental work on animals which eventually resulted in establishing the minimal dose that could be relied upon to make the scalp depilate. This was established to be 8 mg. per kilo of body weight. An effective method of administration was found to be a single dose by the mouth dissolved in sweetened water. Buschke obtained imperfect epilation when the drug was given mixed with food.

The therapeutic value of the treatment has been tested on a large scale in Mexico by Cicero and on a somewhat smaller scale by Buschke in Germany, by others on the Continent, and more recently in England. A very large number of cases altogether approaching 1,000 were reported in 1925, and the results were stated on the whole to be remarkably successful.

My own experience has been of cases of which 10 are still under treatment—a sufficient number to warrant some definite conclusions concerning its value. The technique advocated by Buschke has been followed. I have given 8 mg. 85 mg. and 9 mg. per kilo of body weight dissolved in about 2 oz. of sweetened water. 8 mg. has been found rather too small a dose, and I have generally used one or other of the larger doses, using 9 mg. only in certain circumstances to which I will refer later.

I have employed two preparations of thallium acetate—one made by Marx and Baker, the other by Kahlbaum of Berlin, which is the preparation used by Buschke. I have not been able to observe any obvious difference in the depilatory action of the two drugs. Kahlbaum supplies the drug in tablets containing 1 decigram, 1 centigram, and 1 milligram, so that it is a simple matter to convert the weight of the child in pounds to kilograms, multiply by 85 or 9, and administer the required number of tablets in water.

The effect of this single dose of thallium acetate is well known about the seventh day the hair begins to loosen, and by the fourteenth day it comes out in a most dramatic fashion. By the nineteenth day depilation is complete except for some sparse fine unpigmented but quite long hairs of the lanugo type scattered over the scalp, but found mainly near the hair margin, particularly in the frontal region. These hairs never come out and incidentally they appear never to be infected with ringworm. The eyelashes and eyebrows do not fall though the outer third of the eyebrows thin out occasionally, reminding one of the appearance of leucism in thyroid insufficiency. In adults the pubic and axillary hair and the hair on the arms do not come out with a dose of 8 mg. or 9 mg. per kilo. The infected stump, though absolutely loose, does not fall with the ready ease of the normal hairs. In actual fact most of the hair appears to be the result of slight traction—for example, if the hair brush is used. The stump being very short naturally escapes the limit of traction.

The same failure of the stump to fall out spontaneously also occurs after repeated x-ray depilation, and in such cases adjunct measures have to be used such as the application of some number of adhesive strappings, followed by withdrawal. This is a very important point for attention, for these loose infected stumps may come out eventually and then persistence for a few days or even several weeks after depilation does not necessarily mean that the hair will not be cured, yet it is necessary to use a depilatory treatment all over the scalp with one or two exceptions to guard against reinfection. The infection of the scalp to appear almost immediately. This infection of the scalp must not be stopped until it is certain that the roots of the infected stumps are dead.

Occasionally this infection does not refer to the stump, but comes on with the regrowth of the hair. This is particularly the case in inflammatory ringworms. As a general rule it may be stated definitely that the stumps do not come out as readily as the normal hair except in inflammatory cases, or so well as in a good x-ray depilation. The procedure, then, is as follows: A single dose of thallium

acetate—8.5 or 9 mg per kilo of body weight—is given in sweetened water. From the first day a fungicide ointment is rubbed twice daily all over the scalp. At the time of depilation (seventeenth to nineteenth day) the scalp is examined carefully for infected stumps. As many as possible are removed by means of adhesive stripping in the manner already described, or with epilating forceps. However thoroughly this is done it is certain that some stumps will be left behind. In many cases these will come out spontaneously in the course of time. It is advisable, however, to make a daily examination for stumps and to epilato with forceps, as well as to continue local treatment in all cases for a good fortnight after a careful examination of the scalp has failed to reveal the presence of any evidence of infection. I should like to refer to Dr. Roxburgh's method, which he has recently exhibited, of testing for cure by means of an ultra-violet beam—a method which I am sure will be adopted eventually by all skin clinics.

Regrowth after thallium depilation begins very early, the actual time varies a good deal, but, generally speaking, it begins within a fortnight or less of the deslucium. The point I would like to emphasize is that the chief practical difficulty in the thallium treatment is that the hair grows again so rapidly that particular care must be taken to get at all the infected hairs as quickly as possible and to protect the new hairs with fungicide treatment applied vigorously. This entails a considerable amount of trouble on the part of the doctor or nurse.

The local treatment is of the greatest importance. Buschke advocates the use of 10 per cent sulphur ointment from the first day of treatment. Then at the time of deslucium ointment and tincture of iodine are applied on alternate days. I regret that I did not follow these suggestions of Buschke until recently, and I attribute some failures to this omission. I used at first either mercuric ammonium chloride ointment with 2 per cent of salicylic acid, or Whitfield's benzoic and salicylic acid ointment. Buschke's treatment has been carried out in the last ten cases that have undergone full treatment, and all of these have been cured.

The weighing of the patient and of the drug must be scrupulously accurate. The difficulty of weighing the drug to the nearest milligram may be overcome by buying it weighed up in decigrams, centigrams, and milligrams.

The time should be realized in each case. Sulphur ointment (10 per cent) is rubbed twice or three times daily all over the scalp, and at the time of deslucium this treatment is combined with application of tincture of iodine twice daily on alternate days, and the daily removal of as many loose stumps as possible. It is better to keep the children in bed during the treatment, though most of my cases have of necessity been ambulatory cases.

### Results

I have divided my own cases into four classes: (1) Children aged 3 years and under and for whom early treatment would not be available, 16 cases, all cured. (2) Children over 3 years of age, 46 cases—35 successes, 11 failures. (3) Four of these cases had already been treated with rays without success. All these were successfully treated. One of them was still completely bald, except for the patches which had resisted epilation. The thallium was administered two months after the ray treatment. An interesting feature of this case was that regrowth all over the scalp commenced within a fortnight of the deslucium due to thallium—earlier, I thought, than would have occurred had he been left alone. (4) Six cases were treated with two-thirds of a depilatory dose of thallium and either half or two-thirds of a depilatory ray dose, depilation either failed absolutely or was incomplete in all these cases, except one, in which I am inclined to attribute the depilation to thallium alone. This appears to prove that rays and thallium act in different ways and that they cannot be used to supplement one another. Twelve patients ceased to attend for further observation and treatment after varying periods or attended irregularly. Some of these may have been cured eventually, for they were all supplied with ointment for local treatment. They are excluded from further consideration. Ten patients

have been treated within the past four or five weeks, and are still attending for treatment.

Other observations which appear to me to be of importance are these: Children with stout, coarse, usually black, hair resist thallium depilation more than those with fine hair. I consider that these cases require the larger dose, 9 mg per kilo. I have noticed that the crown depilates rather less readily than the rest of the scalp, so for uniformity of this area also I consider 9 mg advisable.

Thirty-seven cases have been treated with Miv and Baker's thallium, 25 with Kahlbaum's preparation. The results have been 29 successes and 8 failures with the first preparation, 22 successes and 3 failures with the second. Ten children have been treated locally throughout with sulphur and iodine, all with success, and though I cannot be certain that all cases treated by this method will be successful, the results are suggestive. Of 62 cases fully treated and observed throughout, 51 have been successful, 11 have failed, this excludes patients who have not attended for full treatment or have attended irregularly, and the cases in which a ray has been combined with thallium, so that a possible 18 further cases must be added to the failures, though some few of these may have eventually cleared up. Of 10 remaining cases still under treatment 7 have already epilated, they are undergoing sulphur and iodine treatment, and I expect them to be cured.

### Toxic Effects

I do not think sufficient stress was laid upon the toxic side of thallium treatment by those who published the first cases, or, I must confess, by myself in a small series that I published six months ago. Further experience has proved to me that these are not negligible.

There has been great variability in the degree of toxic effects, but very few patients have been entirely free from them (12 cases out of 90). The commonest symptoms are undoubtedly joint pains, particularly in the lower limbs. These pains usually begin about the eighth or tenth day, but occasionally earlier. They pass off by degrees, usually disappearing altogether in three to four weeks. There is in addition frequently loss of appetite, drowsiness, and irritability. These manifestations pass off more gradually than the pains in the joints. In some cases these general manifestations have been almost totally absent, the joint pains being the only trouble. Two of my cases, and possibly more, have unfortunately been seen by practitioners who, unaware of the facts of the case, have diagnosed acute rheumatism. The fall of hair has taken place, regrowth has occurred, and the new hair has become infected. I do not know the explanation of the joint pains, but it is possible that the drowsiness may be due to temporary damage of the thyroid gland. At any rate, it has been shown experimentally by Buschke and by Curtis that this gland suffers severe damage in animals that are given repeated poisonous doses of the drug.

It has been found also that children develop a temporary hypochlorhydria or achlorhydria during thallium treatment. With this information I have attempted to counteract the general symptoms with small doses of thyroid extract and of dilute hydrochloric acid. I have observed, apparently as a result of this, a rapid recovery to their normal condition of the children who have received this treatment. I should add, further, that in spite of this alarming list of symptoms no child that I have treated appears eventually to be any the worse in general health. This is substantiated by the experimental fact that rats and rabbits remain healthy after a depilatory dose of thallium.

Finally, it must be added that very young children are much more tolerant of thallium than older children. This may be because older children require a larger dose, but I do not think this is entirely the reason. My youngest patients have been 1 year old, and have shown no toxic symptoms whatever.

### Pharmacological Action

The very remarkable action of thallium acetate in producing alopecia is, so far as is known, shared by no other substance. The exact mechanism of its depilatory action is not absolutely known, but certain established facts appear to show that this action is upon the sympathetic nervous

The first thirty cases treated at Booth Hall were in the early part of 1927 and were all complete failures. The preparation used was probably stale and inactive, the demand for the drug being negligible at that time. Evidently it does not remain active indefinitely, and we suggest that thallium acetate in contact with the air may slowly become changed into the carbonate.

With a fresh supply of thallium acetate about fifty children have been treated, and with the exception of three all have been successfully depilated. There were three failures where, at the end of twenty-one days, there was only patchy depilation, the remaining hairs being absolutely firm. We cannot explain this, but it is interesting to note that the statement of another observer, that fair children depilate more readily than dark-haired children, is borne out, for the failures were dark children in the proportion of two to one. On the other hand, we have had perfectly satisfactory depilation of a considerable number of dark-haired children.

Signs of thallium toxicum were manifested in five children. Two of these, aged 3 and 6 years respectively, had very transitory albuminuria, the former showed albumin on the thirtieth day only, and the latter on the first and second days after the dose. In the other three children (girls—two aged 11 and one 10) pruritis in the knee-joints and down the tibiae to the ankles arose between the tenth and twelfth days, and were evidently severe. In one there was definite effusion into the right knee-joint, but the two others showed nothing on examination except tenderness and some pain on full flexion. No rise in temperature occurred, but in one girl the pulse rate increased with the onset of pruritis. All three cleared up in less than a week on salicylates, with the methyl salicylate liniment applied locally on lint, they depilated well, and up to the time of their departure to the convalescent home showed no other untoward symptoms. These three girls were the oldest and heaviest children who were given the drug, and consequently received the largest doses. This may give some clue as to the limit at which the method is applicable, since we understand it has been shown that serious toxic signs develop in adults given doses far short of that which would be required to produce depilation. The heaviest child among our cases which depilated without showing any toxic signs weighed 23 kilos, the lightest among the bone and joint cases weighed 23.9 kilos, and the heaviest 32 kilos. The two cases of albuminuria occurred in younger and lighter children.

#### Conclusions

We have in thallium acetate a drug which may have a great future in the treatment of ringworm of the scalp, both in institutions and in private practice, but we consider that more observation is needed before its use becomes general. We do not know the ultimate effects of thallium acetate on the kidneys. The questions which demand answers are: Why does it produce albuminuria in some cases and not in others? Are any changes produced in the kidneys in those who do not show this symptom? Is the e possible irritation which may give the way for future kidney trouble? How soon is all the thallium acetate excreted by the kidneys? We presume it is all excreted in this way, and we need a suitable chemical test for its presence in the urine. We also do not know what the exact changes are which produce the bone and joint symptoms, and, so far, we can only assume from their short duration that no lasting damage is done.

We can say definitely that treatment by thallium acetate, thoroughly carried out, shows a 90 per cent standard of efficiency. Local treatments with tincture of iodine, ointments, etc., are unsatisfactory compared with thallium and x-ray depilation, and thallium has the advantages over the x-rays of producing a speedier and equally efficient depilation, of a speedier occurrence of new growth after treatment, and, so far as we have seen, no permanent alopecia. X-ray depilation is unsuitable for children under 3 years of age, and in these cases thallium is successful. We have dosed a child as young as 10 months. At the other end of the scale we are driven to conclude that there is a limit of body weight beyond which toxic symptoms tend to arise readily. We do not yet know if with this type

of case a lesser amount of the drug per kilo of body weight would be efficient in procuring depilation without the occurrence of such signs, but in the next cases which weigh 23 kilos or over we intend to try seven milligrams per kilo instead of eight.

When applying this method of treatment it is necessary to bear well in mind the following salient points:

- 1 Remember the routine examination of the urine and the nature of possible toxic signs.
- 2 Weigh the child naked.
- 3 The drug must be of recent manufacture, and if the solution method is used, the solution should not be kept more than a day.
- 4 Depilate between the fourteenth and nineteenth days, and above all strip the patches thoroughly as suggested. The old patches should be examined with a lens after this to see that no stumps are left. A few dirty stumps will reinfect the new growth, which comes very quickly.

Our acknowledgments are due to Dr. J. D'Ewart, medical superintendent, for permission to publish our observations, and to Dr. Gibson, visiting dermatologist, for his interest and help in the supervision of the treatment.

## NASAL HEADACHES.\*

BY

E. MILES ATKINSON, M.B., F.R.C.S.,  
BATH, JACKSONIAN PRIZE ESSAYIST, 1926

To bring forward again the well-worn subject of headache may appear to be in the nature of flogging a dead horse, but, in the many papers recently published on this symptom, I have found few references to nasal disease as a possible causative factor. This is my excuse. In what follows I shall omit consideration of those cases in which the headache is obviously part and parcel of some remote nasal infection, and confine discussion to those of Egyptian headache where there is no definite signpost to the cause.

Every medical man frequently has to deal with the type of case to which I refer. Some of the patients suffer almost constantly, and look ill, run down, and toxic, others have violent attacks of headache with periods of freedom, some suffer in silence, as far as any reference to a medical man is concerned. Others seek remedies even where, if they have sought medical advice they will probably have been investigated for bowel trouble, menstral disorders, errors of refraction, and possible sources of toxicæmia such as septic teeth, but comparatively rarely will the nose have been examined. I am far from suggesting that these other conditions are not important and frequent causes of headaches, or that some nasal lesion is more common than any of them, but I wish to suggest that, other possibilities having proved negative, the nose should be thoroughly examined for any possible source of the trouble before labelling the patient as, for example, a case of toxicæmic headache, or of atypical migraine.

There are essentially two conditions in the nose which may give rise to headaches of nasal type—sinus disease and some form of nasal obstruction. The more usual and more important of these is the former, and unsuspected pus held up in one or more of the sinuses is productive of many obscure complaints. There is a widespread belief that accessory sinus suppuration is always associated with nasal discharge, either anterior or posterior, or both, and that in the absence of this symptom sinus disease can be excluded. This is erroneous. Many cases do not show this symptom, and manifest only a concealed focus of sepsis by their general toxicæmic appearance—sallow complexion, listlessness, undue mental and physical fatigue, and the headaches, which may be general or may be of special type according to the sinus involved.

It will make for simplicity to title the various sinuses in turn and describe the kind of headache to be expected in each case.

Disease of the maxillary antrum produces no typical variety; the headache is toxicæmic, sometimes frontal, \*

\* A paper read before the Bath and Bristol Branch of the British Medical Association.

sometimes general, sometimes described as neuralgic, and increasing usually towards the end of the day. It is often thought to be due to eye-strain, but on close question the patient may confess to frequent colds, which are apt to be worse on one side than the other, and that at such times there is some pain in the corresponding cheek.

A lady aged 43 was sent to me for investigation because of arthritis in the shoulder on transillumination it was found that the antrum on one side was dark. She then said that ever since she was a girl of about 12 she had suffered from headaches and from pain beneath the corresponding eye, especially if she had a cold, all had been called neuralgia. She looked thoroughly toxic and said she never felt really well but was so busy that she had no time to feel ill. Puncture of the antrum yielded foul inspissated pus. The antrum was drained intranasally and gradually cleared up. This was last autumn. She has gone through the winter without a cold, has been free from headache for the first time for years, and looks and feels quite a different woman.

In this case there was only discharge from the antrum during a cold, when it was not noticed. Sometimes no history of discharge or offensive smell can be obtained.

A man aged 62 was sent on account of two or three recent attacks of laryngitis, with the warning that he was always exceedingly nervous and suffered at times from incapacitating headaches. He had pus in one antrum, very foul, probably originating from a carious upper molar tooth which had been extracted some twenty years previously. Question him as one might he would not admit to any nasal symptoms. After some trouble he and his doctor were persuaded to agree to intranasal drainage of the antrum since then (18 months) he has only had one attack of headache and that not severe when he caught cold and his antrum flared. His laryngitis has not returned.

**Frontal sinus disease** is usually associated with headache of a very definite type. The pain is situated in the frontal region immediately above the eye, and may spread over the whole of the affected side of the head—a true hemi-crania. Hence it is often mistaken for migraine. In severe cases it may extend to the other side of the forehead, and thence all over the head, though only one frontal sinus is involved. It occurs typically in the morning, starting soon after the patient gets out of bed, and gradually subsiding to disappear about lunch time. It may be so severe at the onset as to cause vomiting and some interference with vision on the affected side, thus making the mimicry of migraine more complete. But the typical battlemented spectra of migraine are absent. Frontal sinus headaches often occur in bouts in chronic cases, the headache coming on every morning for a fortnight or three weeks, but gradually diminishing in intensity and then disappearing for weeks or months. These bouts are initiated by some catarrhal infection, which causes the sinus to flare up, and the headache diminishes coincidentally with the superimposed catarrh. The diagnosis can often be made on the history, but should always be confirmed by a skiagram. There is usually little or nothing to be seen inside the nose. A deviation of the septum to the affected side is common, and during an attack there may be oedema of the middle turbinate with, possibly, some pus exuding beneath it. Often both these signs are absent. An interesting case of this type occurred a few weeks ago in a boy of 16—unusually young for such cases.

This boy had suffered from typical frontal attacks for two or three years and his father had before him. The tonsils had been removed on account of the headaches but without benefit and he was then labelled migraine—no doubt the family history led to this. Then he started a cold at school and had another of these attacks. His school doctor, an alert clinician, diagnosed an infection of the frontal sinus. But examination of his nose showed no oedema of the turbinate nor could any suspicion of pus be obtained from beneath it, even after the most thorough shrinking with cocaine. A skiagram, however, showed the frontal sinus on the affected side blurred and hazy, the fronto-nasal duct was acutely kinked and narrowed by a large fronto-ethmoidal cell which was preventing drainage and ventilation. When this and the other anterior ethmoidal cells were curetted away there was a free passage into the frontal sinus which contained mucus and flavo-purulent pus—obviously an acute catarrh superimposed upon an infection of long standing. He is now doing well and has had no more headache.

The anterior ethmoidal cells are frequently involved at the same time as the frontal sinuses, and then the headache is apt to be more persistent and not so typically matutinal,

while eye symptoms are, in addition, not uncommon, such as some blurring of vision or a sensation of pressure or of throbbing in the orbit. This often leads to the diagnosis of a refractive error, if one is present, as the cause of the headache, and when correction of such error by glasses fails to relieve, the case is again usually labelled migraine. It is, therefore, of importance that all cases of hemi-crania in which the symptoms are not those of classical migraine, and are not relieved by suitable glasses, should have a thorough examination of their nasal sinuses before being left to their fate. They should be seen by a rhinologist in the second place as automatically as by an ophthalmologist in the first. In these cases, as in those affecting the frontal sinus only, examination of the nose often reveals very little, and recourse has to be had to a skiagram for diagnosis.

A middle-aged lady developed all the symptoms of an acute infection of the antrum following extraction of an upper molar tooth, but in addition to this she told a story of years of headache with more recently failing or rather blurring of vision to such a degree that she had had to give up needlework almost entirely. This suggested that there was something more than an affection of the antrum and a skiagram showed infection of all the anterior group of sinuses. An intranasal operation upon the ethmoids to drain them and give access to the frontal and at the same time upon the antrum produced an extraordinary change. She lost her headaches and tiredness, her sight rapidly improved so that she could with ease do fine embroidery, she gained in weight, improved in colour and said when last seen some three months ago, that her friends could recognize her.

These two cases of frontal sinus disease, which had been unrecognized for long periods, indicate what can be done in favourable cases in the way of relieving headache. Unfortunately all cases do not respond so well. Many patients, even after free drainage continue to have headaches, perhaps not so severe, but quite enough to render their lives a burden to them, and not infrequently one fails to relieve them even by external operative procedures. Many relapse into complete invalidism and some even develop suicidal tendencies. In others, again, one fails entirely to stay the progress of the infection, so that ultimately it may spread to the intracranial contents. My impression, unsupported by statistical evidence, is that those cases of frontal sinus headache with a patent ostium and with obvious discharge from the sinus are the least satisfactory in their results, while those in which headache is the only indication of the disease, in fact the closed cases with which this paper deals, are the most satisfactory.

**Vacuum Frontal Headache**—Another cause of frontal headaches is the condition named by Sluder vacuum frontal headache. It results from closure of the fronto-nasal duct so that the air in the sinus is absorbed, producing a partial vacuum and congestion of the lining mucosa. This causes the thin bony floor of the sinus to become very sensitive to pressure, the point of maximum tenderness being at the thinnest part—that which lies internal to and behind the point of attachment of the pulley of the internal oblique muscle (Ewing's sign). Consequently, therefore, movements of the eyes aggravate the pain, and this is a very characteristic feature. These cases are not very uncommon, they are partly anatomical and partly pathological. A deviation of the septum may so narrow the nasal passage as to pressure the middle turbinate against the outer wall of the nose—in it of a cause or pain. If to this is added a catarrhal swelling of the mucous membrane the orifice of the duct may be completely blocked and headache result or the bone and covering mucosa or the middle turbinate may be the seat of an inflammatory process causing oedema or polypoid formation, which will block the duct. A patient who had an acute infection of the antrum stated that he had had typical frontal headaches for several days (great oedema of the middle turbinate was causing the block). The headache went away soon as the antrum was drained and the oedema began to subside. In cases due to a temporary constrictor swelling no judicious application of cocaine is likely to

be of long use a patient who is suffering from a vacuum headache may be relieved by the application of a vacuum to the anterior end of the middle turbinate with a vacuum

The first three cases treated at Booth Hill were in the early part of 1927 and were all complete failures. The preparation used was probably stale and inactive, the demand for the drug being negligible at that time. Evidently it does not remain active indefinitely, and we suggest that thallium acetate in contact with the air may slowly become changed into the carbonate.

With a fresh supply of thallium acetate about fifty children have been treated, and with the exception of three all have been successfully depilated. There were three failures where, at the end of twenty-one days, there was only patchy depilation, the remaining hairs being absolutely firm. We cannot explain this, but it is interesting to note that the statement of another observer, that fair children depilate more readily than dark-haired children, is borne out, for the failures were dark children in the proportion of two to one. On the other hand, we have had perfectly satisfactory depilation of a considerable number of dark-haired children.

Signs of thallium toxicæmia were manifested in five children. Two of these, aged 3 and 6 years respectively, had very transitory albuminuria, the former showed albumin on the thirteenth day only, and the latter on the first and second days after the dose. In the other three children (girls—two aged 11 and one 10) pains in the knee-joints and down the tibiae to the ankles rose between the tenth and twelfth days, and were evidently severe. In one there was definite effusion into the right knee-joint, but the two others showed nothing on examination except tenderness and some pain on full flexion. No rise in temperature occurred, but in one girl the pulse rate increased with the onset of pain. All three cleared up in less than a week on salicylates, with the methyl salicylate liniment applied locally on hut, they depilated well, and up to the time of their depilation to the convalescent home showed no other untoward symptoms. These three girls were the oldest and heaviest children who were given the drug, and consequently received the highest doses thus far given, some this is to the limit at which the method is applicable, since we understand it has been shown that serious toxic signs develop in adults given doses far short of that which would be required to produce depilation. The heaviest child among our cases which depilated without showing any toxic signs weighed 23 kilos, the lightest among the bone and joint cases weighed 23.9 kilos, and the heaviest 32 kilos. The two cases of albuminuria occurred in younger and lighter children.

#### Conclusions

We have in thallium acetate a drug which may have a great future in the treatment of ringworm of the scalp, both in institutions and in private practice, but we consider that more observation is needed before its use becomes general. We do not know the ultimate effects of thallium acetate on the kidneys. The questions which demand answers are: Why does it produce albuminuria in some cases and not in others? Are any changes produced in the kidneys in those who do not show this symptom? Is there possibly mutation which may pave the way for future kidney trouble? How soon is all the thallium acetate excreted by the kidneys? We presume it is all excreted in this way, and we need a suitable chemical test for its presence in the urine. We also do not know what the exact changes are which produce the bone and joint symptoms, and, so far, we can only assume from their short duration that no lasting damage is done.

We can say definitely that treatment by thallium acetate, thoroughly carried out, shows a 90 per cent standard of efficiency. Local treatments with tincture of iodine, ointments, etc., are unsatisfactory compared with thallium and hair depilation, and thallium has the advantages over the others of producing a speedier and equally efficient depilation, of a speedier occurrence of new growth after treatment, and, so far as we have seen, no permanent alopecia. Hair depilation is unsuitable for children under 3 years of age and in these cases thallium is successful. We have dosed a child as young as 10 months. At the other end of the scale we are driven to conclude that there is a limit of body weight beyond which toxic symptoms tend to arise readily. We do not yet know of with this type

of case a lesser amount of the drug per kilo of body weight would be efficient in procuring depilation without the occurrence of such signs, but in the next cases which weigh 23 kilos or over we intend to try seven milligrams per kilo instead of eight.

When applying this method of treatment it is necessary to bear well in mind the following salient points:

- 1 Remember the routine examination of the urine and the nature of possible toxic signs.
- 2 Weigh the child naked.

Since then (six months) he has only had one attack of headache and that not severe when he caught cold and his antrum flared. His laryngitis has not returned.

**Frontal sinus disease** is usually associated with headache of a very definite type. The pain is situated in the frontal region immediately above the eye, and may spread over the whole of the affected side of the head—a true hemicrania. Hence it is often mistaken for migraine. In severe cases it may extend to the other side of the forehead, and thence all over the head, though only one frontal sinus is involved. It occurs typically in the morning, starting soon after the patient gets out of bed, and gradually subsiding, to disappear about lunch time. It may be so severe at the onset as to cause vomiting and some interference with vision on the affected side, thus making the mimicry of migraine more complete. But the typical battlemented spectra of migraine are absent. Frontal sinus headaches often occur in bouts in chronic cases, the headache coming on every morning for a fortnight or three weeks, but gradually diminishing in intensity and then disappearing for weeks or months. These bouts are initiated by some catarrhal infection, which causes the sinus to flare up, and the headache diminishes coincidentally with the superimposed catarrh. The diagnosis can often be made on the history, but should always be confirmed by a skiagram. There is usually little or nothing to be seen inside the nose. A deviation of the septum to the affected side is common, and during an attack there may be oedema of the middle turbinate with, possibly, some pus exuding beneath it. Often both these signs are absent. An interesting case of this type occurred a few weeks ago in a boy of 16—unusually young for such cases.

This boy had suffered from typical frontal attacks for two or three years and his father had before him. The tonsils had been removed on account of the headaches but without benefit and he was then labelled migraine—no doubt the family history led to this. Then he started a cold at school and had another of the attacks. His school doctor, an alert clinician, diagnosed an infection of the frontal sinus. But examination of his nose showed no oedema of the turbinate nor could any suspicion of pus be obtained from beneath it even after the most thorough brushing with cocaine. A skiagram however showed the frontal duct was affected, also blurred and hazy the fronto-nasal duct was acutely kinked and narrowed by a large fronto-ethmoidal cell which was preventing drainage and ventilation. When this and the other anterior ethmoidal cells were curetted away there was a free passage into the frontal sinus which contained muco-pus and flake pus—obviously an acute catarrh superimposed upon an infection of long standing. He is now doing well and has had no more headache.

The anterior ethmoidal cells are frequently involved at the same time as the frontal sinuses, and then the headache is apt to be more persistent and not so typically matutinal,

while eye symptoms are, in addition, not uncommon such as some blurring of vision or a sensation of pressure or throbbing in the orbit. This often leads to the diagnosis of a refractive error, if one is present, as the cause of the headache, and when correction of such error by glasses fails to relieve, the case is again usually labelled migraine. It is, therefore, of importance that all cases of hemicrania in which the symptoms are not those of classical migraine, and are not relieved by suitable glasses, should have a thorough examination of their nasal sinuses before being left to their fate. They should be seen by a rhinologist in the second place as automatically as by an ophthalmologist in the first. In these cases, as in those affecting the frontal sinus only, examination of the nose often reveals very little, and recourse has to be had to a skiagram for diagnosis.

A middle-aged lady developed all the symptoms of an acute infection of the antrum following extraction of an upper molar tooth but in addition to this she told a story of years of headache with more recently failing or rather blurring of vision to such a degree that she had had to give up needlework almost entirely. This suggested that there was something more than an affection of the antrum and a skiagram showing in evidence of all the anterior group of sinuses. An intranasal operation upon the ethmoids to drain them and give access to the frontal and at the same time upon the antrum produced an extraordinary change. She lost her headaches and tiredness, her eyes rapidly improved so that she could with ease do fine embroidery. She gained in weight improved in colour and did what she had not done some three months ago that her friends scarcely recognized her.

These two cases of frontal sinus disease in which had been unrecognized for long periods indicate what can be done in favourable cases in the way of relieving headache. Unfortunately, all cases do not respond so well. Many patients, even after free drainage continue to have headaches, perhaps not so severe, but quite enough to render their lives a burden to them, and not infrequently one fails to relieve them even by external operative procedures. Many relapse into complete invalidism and some even develop suicidal tendencies. In others, again, one fails entirely to starve the progress of the infection, so that ultimately it may spread to the intracranial contents. My impression unsupported by statistical evidence is that the cases of frontal sinus headache with a patent osium and with obvious discharge from the sinus are the least satisfactory in their results while those in which head ache is the only indication of the disease, in fact the closed cases with which this paper deals, are the most satisfactory.

**Vacuum Frontal Headache.**—Another cause of frontal headaches is the condition named by Sluder vacuum frontal headache. It results from closure of the fronto-nasal duct so that the air in the sinus is absorbed, producing a partial vacuum and congestion of the lining mucosa. This causes the thin bony floor of the sinus to become very sensitive to pressure, the point of maximum tenderness being at the thinnest part—that which lies internal to and behind the point of attachment of the pulley of the internal oblique muscle (Ewing's sign). Consequently, therefore, movements of the eyes aggravate the pain, and this is a very characteristic feature. These cases are not very uncommon they are partly anatomical and partly pathological. A deviation of the septum may so narrow the nasal passage as to prevent the middle turbinate against the outer wall of the nose—in it is a cause of pain. If to this is added a catarrhal swelling of the mucous membrane the orifice of the duct may be completely blocked and headache result or the bone and covering mucosa of the middle turbinate may be the seat of an inflammatory process causing oedema or polyp formation, which blocks the duct. A patient who had an acute infection of the antrum stated that he had had typical frontal headaches for several days. Great oedema of the middle turbinate was causing the block. The inflammation was soon in the antrum was drained and the oedema subsided. In cases due to anatomical factors or to inflammation the judicious application of cocaine is of value.

I am, I think, justified in saying that the cases of vacuum frontal headache are not infrequently overlooked and that with a careful examination of the nose and a skiagram the diagnosis can be made.

swollen, and his nasal passages were very narrow. Cocaine was applied preparatory to removing the polypus, which I suspected of being the cause of the trouble by blocking the duct, and while waiting for it to act he suddenly sat up and said "My headache has gone! I felt it go this moment." The cocaine had caused the mucosa to shrink sufficiently to allow air to enter beside the polypus. The polypus was removed, and he attended to his business. He has had no more trouble.

Such dramatic cures are regrettably rare. More usually relief is obtained gradually by means of the usual remedies for catarrh, or by an operation to correct a septal deformity or remove the anterior end of the middle turbinate.

The posterior group of sinuses are less often the cause of chronic headache, and the pain caused by chronic infection in them is not characteristic. It has been said that suppuration of the sphenoidal sinus causes a "bursting" temporal headache or pain in the occipital region, but this does not always happen. However, a complaint of headache of this or any other type, especially if associated with post-nasal catarrh or crusting, would raise a suspicion of involvement of the posterior group and lead to an x-ray examination. I have never come across a case of otherwise symptomless headache of which the sphenoidal sinus was the cause, but they are said to exist, and adequate drainage should produce rapid relief of symptoms, for the sphenoidal sinus is one of the most satisfactory to deal with.

Atrophic rhinitis is associated at times with severe headaches. There are cases of this condition in which there is no fetor, and in which the crusting in the nose seems to be a minor annoyance. The main complaint is of severe generalized headache, and in the absence of fetor, or of any mention by the patient of nose trouble, the rhinitis may be overlooked. The cause of the headaches, of course, is that not only the mucosa of the nasal passages is atrophic and crusted, but all the sinuses also are full of crusts. If the crusting has extended to the pharynx and larynx, as it may, the cause of the headache will be apparent.

Nasal obstruction may seem at first sight beyond the limits of this paper, yet it is surprising what a degree of obstruction patients will tolerate seemingly without distress, and will complain of their headache and not of their nose.

A man came one day with a polypus protruding from the anterior nares, having been unable to breathe properly through his nose for years, or at all for months. He said that he could not stand prolonged or extensive operative treatment, as he was a very sick man, having been under treatment for years for chronic headaches, neuralgia, and gastro-intestinal troubles. He was thin, pale, and sunken-eyed. He had never mentioned his nasal trouble to anyone, and his slightly nasal voice had apparently not attracted attention. He was persuaded to consent to having the nose cleared of polypus, which was done bit by bit under local anaesthesia, and took months, but since he has acquired nasal respiration and ceased to swallow mucus his troubles have vanished.

Patients with severe septal deviations will do the same thing.

An educated man of 23 said that he did not know he had nasal obstruction and was only persuaded with difficulty to see a rhinologist by his doctor, who had by chance seen him sleeping with his mouth wide open and had found out his trouble. Yet he has such a gross deformity that he cannot breathe at all through one nostril and only very badly through the other. He suffers from frequent headaches, as do most cases of severe septal deformity. Complete submucous resection produced an excellent result.

A word of warning may not be out of place. There are many sufferers from headache, and there are even more people with minor septal deformities. The two are not necessarily related. It is scarcely an exaggeration to say that a perfect septum does not exist. Given the right case, however, and a complete operation, which is often far from easy, and the results are excellent. The operation has fallen rather into disrepute because it is sometimes performed ill-advisedly and incompletely, and an inadequate septum operation is worse than none at all.

#### Summary

The thesis has been that many cases of chronic recurrent headache are of nasal origin though there are no obvious signs of nasal disease, that many are missed because their

incidence is not sufficiently appreciated, and that therefore the nose should take a place with the eyes in a mental list of possible aetiological factors in such cases. Some clinical material has been brought forward to back the contention that more cases of headache are due to nasal disease than is generally realized, and that the rhinologist can often help heads as well as noses.

## THE ETIOLOGY OF FIBROUS STRICTURE OF THE URETHRA

BY

ANDREW O. ROSS, M.D.,

MEDICAL OFFICER, LIVERPOOL SEAMEN'S DISPENSARY

STRUCTURE of the oesophagus and stricture of the rectum are rarely diagnosed without some effort being made to eliminate the possibility of syphilis acting as a determining factor in their etiology, but, strangely enough, I have never heard it whispered that stricture of the urethra is associated with syphilis. Recurring or successive attacks of gonorrhoea have been held to account for most cases, while some few have been associated with physical or chemical trauma.

Fifty consecutive cases of stricture of the urethra have been examined thoroughly at the Seamen's Dispensary, Liverpool. Every case of chronic urethritis in the male was examined by the urethroscope, and if stricture tissue was found the blood was examined. It is well known that a considerable number of apparent infections with gonorrhoea are in reality infections with syphilis also, although no external signs of syphilis are present then or later—that is to say, that the syphilis is latent from the beginning, and there is neither primary ulcer nor secondary syphilides. The Wassermann reaction is the only method of diagnosis, and a second confirmatory test is absolutely essential.

Of the fifty cases of stricture under review, twenty-one conformed to this type. Twelve others gave a history of penile ulcer during or before the attack of gonorrhoea, and the blood Wassermann test was positive. Six others gave a history of treated syphilis and gonorrhoea, and their blood Wassermann reactions were returned as "negative." One man was sent by a general practitioner to have his blood tested, as his wife had a history of several miscarriages, followed by five full-time children who were born dead or who survived birth for a few hours only. This patient attended twice, stricture tissue was found at 5 cm and 11 cm from the meatus, and his blood reaction was reported negative. Had he returned again a provocative injection of neosalvarsan might have given a positive reaction, as the gonorrhoeal infection was eighteen years old. Ten cases of stricture gave no history of syphilis, and the Wassermann reaction in the serum was returned as negative.

#### Analysis of 50 Cases of Stricture of the Urethra

Wassermann reaction positive	33=66%
History of syphilis, Wassermann reaction negative	6=12%
No history of syphilis, Wassermann reaction negative	11=22%

Stricture of the urethra, therefore, is more common in cases which have coincident syphilis and gonorrhoea, and it is good practice to ascertain the Wassermann reaction of the blood in all cases of stricture. In cases of long duration a negative Wassermann reaction may become positive after a provocative dose of neosalvarsan.

The pathology of the condition is probably that the inflammation of the mucous membrane by the gonococcus provokes a greater response in the submucosa of syphilides, that an abnormal number of small round cells is developed, and that these subsequently form the urethral stricture.

In view of this connexion between syphilis and stricture it is not surprising to find that cases of resistant stricture having a positive Wassermann reaction become amenable to dilatation after a course of antisyphilitic treatment with bismuth alone, or neosalvarsan and bismuth. One patient, who on four different occasions had been diagnosed as a case of impermeable stricture, was dilated up to 45 Charrière within three months of the inception of antisyphilitic treatment.

### MEDICAL, SURGICAL, OBSTETRICAL.

#### MINERS' NYSTAGMUS IN A SURFACE WORKER

Dr FREDLAND FERGUS in a recent communication referred to the occurrence of occasional cases of miners' nystagmus among pithead workers, but stated that no such case had come within his own experience. If any undoubted case of miners' nystagmus can be demonstrated in which the disease developed in spite of adequate illumination of the working place, doubt is at once thrown on the validity of the deficient light theory of the causation of the disease.

T F a miner aged 47, first came under my care in February 1926 complaining of cough, expectoration and loss of weight which were soon found to be due to early pulmonary tuberculosis. With the exception of trench fever in France he had never had any illness. He did well under sanatorium treatment and was able to resume work in January, 1927.

He had an attack of influenza during the last epidemic and has not been able to return to work since. I noticed nystagmoid movements in June 1927. The man on questioning admitted that his eyes had felt weak for a few days and that he felt giddy in the twilight. Apart from the fact that he has pulmonary tuberculosis he is a typical case of miners' nystagmus but he has never been underground. An agricultural labourer before the war he only went to the pit in 1919. Since then he has been employed on the top, working in daylight but exposed to coal dust.

It is just possible that the nystagmus may be due to an intracranial tubercle but there is nothing to support this idea, and I personally regard the case as one of true miners' nystagmus. It is possible that the nystagmus was due to a toxin in the coal dust as Dr Fergus suggests but in any case illumination could have nothing to do with it.

HENRY S. RUSSELL, M.B. B.Sc.

Langley Mill nr Nottingham

#### TREATMENT OF GONORRHOEA

The following case seems to have a special interest in illustrating the value of early and energetic treatment in cutting short an attack of gonorrhoea and in the prevention of its sequelae.

On May 5th a man aged about 43 consulted me for gonorrhoea. He informed me that the incubation period was about a week and that it was his first attack. He stated that on May 3rd he had had itching of the meatus and on the following day a discharge. On examination I found that he had a thick yellowish white discharge and signs of acute inflammation with painful and difficult micturition. I thought over the advisability of giving injections and decided on hydrogen peroxide (10 vols.) (this I found too painful to continue until a solution of cocaine was added). The first injection was given on May 6th; on the next day there was much less discharge and redness. I repeated the treatment. One injection was given each day up to May 10th when the discharge had ceased. Two days later there was still no discharge and the meatus appeared healthy, the smarting and irritation had also disappeared. The only additional treatment was liquor copalivae by the mouth, and fairly large doses of sodium bicarbonate and tincture of bromocresol.

According to the usual teaching, when the discharge is copious and scalding continues injections are harmful and should not be employed, either because of the pain caused by the injection or the danger of spreading the infection backwards. A great number of antiseptics are recommended for use as injections in the later stages of the disease, but I have not seen mentioned hydrogen peroxide (10 vols.), which is a powerful, non-poisonous, and oxidizing agent, and is practically harmless in some respects it even rivals corrosive sublimate. It is a powerful antiseptic and does not precipitate albumin, on coming into contact with pus it destroys bacteria of all kinds and causes activity in the tissues which leads to rapid healing. At the same time brisk effervescence occurs. This last point is very important, because, if the injection is retained in the urethra by compressing the glands against the nozzle of the syringe, the peroxide works under considerable pressure, understanding the urethra with its numerous follicles. As is well known, much of the intractability of gonorrhoea is due to invasion of the numerous follicles which open on the mucous surface of the urethra, when the inflammation gives rise to cysts and invades the connective tissue. The cure has practically passed beyond reach. Such after-

effects then appear as a stricture and the invasion of the blood stream. In my opinion the best method of cure is to get the gonococci early and treat them rough. I understand that hydrogen peroxide can be obtained in any strength up to 50 per cent, or a 100 volume solution—perhydrol. Patients will tolerate much stronger antiseptics in the early stages than can be applied later on, and, moreover, they often discontinue treatment after the discomfort has ceased and remain a great source of danger to others for years afterwards. They are much more likely to come for treatment in the painful or acute stage, and this is the best time to deal with the infection, before it escapes out of the reach of antiseptics. Perhaps others with greater experience would give their opinion on this subject.

## Reports of Societies

### THE ROYAL MEDICO-PSYCHOLOGICAL ASSOCIATION

#### ANNUAL MEETING AT EDINBURGH

The eighty-sixth annual meeting of the Royal Medico-Psychological Association took place at the Royal College of Physicians and the University Edinburgh during the week commencing Monday July 18th. The business portion was presided over by Lieut Colonel J. R. IGOY C.B.E. the retiring president, and he was succeeded in the chair by Dr HAMILTON MARR of the General Board of Control for Scotland. At the business meeting it was announced that the next Maudsley lecturer would be Sir John Macpherson.

On July 18th the new president delivered his annual address, taking as his subject, "Dante and Pabelais: an account of two mediaeval physicians, with a summary of their philosophy."

#### Dante and Pabelais

Dr Marr said that not only was Pabelais qualified to practice medicine, but he did so in the city of Lyon and wrote there on medical subjects. To call Dante a physician, however, needed some explanation, he was included in a list of members of the art of medicine and the apothecaries of 1297, but there was no record that Dante ever practiced medicine though he studied it and qualified himself to be a practicing physician. There were in his works numerous references bearing his practical knowledge of medicine his accuracy and scientific observation. Some of these he pointed out. It was essential for a Doctor of Paris in the day to have a knowledge of astrology and astronomy and Dante was a firm believer in the influence of the stars on human destiny as some of the extracts would show.

Dante was an exile from Florence for political reasons, Rabelais was persecuted for his classical studies. The humour and temperament of Rabelais were of a type which did not leave him wholly excusable on the ground that his life would have been endangered had he resorted to a verbal embroidery of nonsense and iniquity he had an impish disposition and would play on words in such a manner as to overstep the bounds of decency. Dante was of a different temperament and when he used words which were unseemly they corresponded with the matter he was treating. Also his type of humour was different from that of Rabelais as it was whimsical. Dante and in the Dr Morrell that Dante obtained for his ultimate end, blessedness of this life which was figured in the earthly paradise and his in the otherworldly which consisted in the fruits of the Divine life in the heavenly paradise. The former much to be desired following philosophical teaching in accordance with the moral and intellectual virtues. I quote from Dr Marr the utmost limit of the only province to which the psycho- and prehistoric truth travel in the course of life. The moral nature of the Inferno was modelled on the Ethics of Aristotle but the order of Purgatorio was Platonic, and the results were considered according to the cause. The speaker gave an interesting analysis of the

works. The works gave graphic pictures of the mental agony of human souls which had chained themselves and refused to leave the darkness of ignorance and vice, wasting their time on fleeting material attractions.

The conclusions of Ribelsius could be stated as follows: work, seek, study, instruct your-elves. In arriving on the work of your predecessors you will go further than they. Time brings new knowledge. Truth is the daughter of time, but in seeking truth do not isolate yourself from your fellow men. Love each other.

Both Dante and Ribelsius recognized the bondage of the intellect, and both pointed out how easy it was to descend to perpetual darkness, how difficult to cast off intellectual bondage, while both led to an earthly paradise, where, drinking of the streams of Icthe and of Pinnoc, the memory of evil was lost, and the good which was overlaid and withered was resurrected, and philosophy was rendered pure and disposed to mount to the stars.

On the mornings of July 20th, 21st, and 22nd the members of the Royal Medico-Psychological Association took part in the discussions held by the Mental Diseases Section of the British Medical Association, on the subjects of chronic sepsis as a cause of mental disorder, epidemic encephalitis, and the Report of the Royal Commission on Lunacy and Mental Disorder.

On July 22nd, at Morningside Royal Hospital, a panel bust of Philippe Pinel was unveiled by Sir Arthur Rose, chairman of the General Board of Control of Scotland, and during the week visits were paid to the Bangour Village Mental Hospital and Morningside, a fine exhibition of handicraft wrought by the patients being on view at the former institution. On the evening of July 20th members dined together at the Royal College of Physicians.

At the spring meeting of the Forfarshire Medical Association, held at Arbroath Infirmary, with the president, Dr R. C. Blair, in the chair, Dr Gilchrist contributed an appreciation of the work of Professor Shapley. It was of interest at this time, he said, to recall that William Shapley, who at University College, London, carried on the traditions of Padua, was one of the teachers of Lister. Shapley was born at Arbroath in 1802, and from Arbroath High School went to Edinburgh University in 1815. After studying in London and Paris he took his M.D. at Edinburgh in 1823, and then for a time assisted his stepfather, Dr Arrott, in his practice in Arbroath. In 1827 he returned to the Continent, and later, after a period of extramural teaching, was called to University College, London. There he was a professor for thirty-eight years. He died in 1880, and was buried in Arbroath Abbey. Dr Gilchrist then showed an unusual case of keloid occurring in a scar after operation for appendicitis. A boy at the age of 12 was operated on for acute appendicitis. Two years later a keloid developed in the scar and was excised. Now, four years after the original operation a large new growth of scar tissue, mostly nodular, occupied the site of the operation scar, while there were smaller nodules in the scars of the sinuses. On one leg he had two scars, the results of accidents before and after his appendix operation. The former was a healthy cicatrix, the latter showed keloid growth. Dr Yule read notes on three cases of infusception, all of the ileo-ileal type. In two of these the "tumour" was situated in the left half of the epigastrium. He emphasized the necessity of examining such cases under an anæsthetic. Dr Yule also read notes on an unusual development of appendicitis. After an initial febrile illness the patient, a boy, had shown no symptoms for a fortnight. Thereafter he passed loose stools containing mucus, and on examination there was found a marked bulging of the plicæ, resembling that of a woman in the second stage of labour. Laparotomy showed that the appendix was very long and that its tip dipped into the pelvis, where it was lost in an abscess cavity. Dr J. L. G. Thomson read a paper on perforation of duodenal ulcer. It had been his experience that a considerable proportion of cases of duodenal ulcer had no symptoms of dyspepsia prior to perforation. Three of his five most recent cases had no history of indigestion, and had remained free since operation. Dr Thomson also showed a case of pre-tibial oedema with optic atrophy. The patient, a man of 43, had argyll Robertson pupils, but no incoordination of the limbs and no Pambertism. The Wassermann reaction was positive and the cerebrospinal fluid showed a lymphocytosis. He had come under observation because of rapid deterioration of vision. A demonstration of radiograms by Dr Laing concluded the meeting.

## Ribelsius.

### THE LIFE AND WORK OF SIR PATRICK MANSON

Sir Patrick Manson was one of the greatest of medical pioneers, and his *Life*,<sup>1</sup> written by Dr. Manson-Barm and Colonel Alcock, two workers in the same field long associated with him in the London School of Tropical Medicine that Manson founded, cannot fail to be of the greatest interest not only to workers in that field but to medical men generally, to administrators in tropical countries, and indeed to the intelligent layman everywhere. The story is fascinating and has been told here within a reasonable compass, the two authors have produced an eminently readable and sympathetic account of the "father of tropical medicine," as he has justly been called, it will be treasured by the now numerous band of workers in the tropical vineyard.

After a brief account of his early years, and of his going to China to practise within a few months of taking his medical degree in Aberdeen his remarkable early work on filariasis, when an isolated medical practitioner in Amoy, is related, the account being founded on his own extensive notebooks. Here, with little apparatus save a microscope, and without any previous training in tropical medicine, he laboured to good effect in tracing the mosquito cycle of *Filaria bancrofti*, illustrating once more the far greater importance of the man than the laboratory, as, indeed, Manson himself pointed out. The modesty of true greatness is well shown by his statement in a letter of 1879 that, "Man, like myself, in general practice, are but poor and very slow investigators, crippled as we are with the necessity of making our daily bread." We are next shown him in Hong-Kong, founding a medical college, at the opening of which he made a speech remarkable for its insight into Chinese character. After twenty-three years in China we find him returning, a comparatively wealthy man, to a country life in Scotland, with his favourite hobbies of shooting and fishing. Fortunately for medicine the depreciation of the Chinese dollar compelled him to embark in practice in London, where he had up-hill work until he became physician to the Albert Dock Hospital, where he made indefatigable use of the opportunities for investigating the life histories of tropical parasites, and did so much to lead "medical education back to those solid biological foundations from which it has been inclined to stray," as the authors happily put it.

Manson had felt the lack of instruction in tropical diseases before going to practise in China, and when on leave in 1875, for want of any teaching in the subject, he had gone to the British Museum library to study, there he first learned of Lewis's discovery of the *Filaria sanguinis hominis*, which he followed up with such success. He now set himself to found the London School of Tropical Medicine, and gathered round him young men who have since proved the wisdom of his choice by their own original work, much of it inspired by his own remarkable foresight and powers of induction, as illustrated by the verification of several ingenious hypotheses he put forward regarding the life histories of various helminths, as is brought out in this book.

It was during this period that he adumbrated the mosquito theory of malaria in his Goulstonian Lectures, and, as he aptly put it, "he discovered Ross," and converted him into a brilliant experimenter in the truth of the hypothesis. The enthralling story of Manson's four years' labour as guide, philosopher, and friend during Ross's epoch-making researches is well told by means of numerous extracts from Manson's letters to Ross, and Ross's early acknowledgements of Manson's invaluable assistance are quoted, in one of them Ross likened himself to the astronomer directed by an actioner. It is also said that it was due to Manson's influence that, as soon as the military exigencies in India permitted, Ross was put on special duty to complete his work, Manson advised him to work with the protozoa of birds, and thus Ross was enabled

<sup>1</sup> The Life and Work of Sir Patrick Manson, by Dr. Philip H. Mearns, D.S.O., M.D., F.R.C.P., and A. Alcock, C.I.E., LL.D., Aberdeen, F.P.S., Hieut. Colonel I.M.S. (ret.), London, Cassell and Co., Ltd. 1927 (Demy 8vo, pp. xv + 273, 12 plates 16s. net)

to advance beyond Manson's original hypothesis and proved that new infections were produced by rejection of a stage of the parasite by the bites of the insects. This is an example of the happy conjunction of two very original minds in winning for the British race the credit for a great scientific discovery; this Manson was anxious to secure, as is clearly shown by his letters here recorded.

Lastly, we are shown that after Manson's retirement from active work in 1912 as the result of increasing infirmities due to nearly life-long gout, he continued to take the closest interest up to a few weeks before his death in the school which he founded; it remains a monument to his genius. This brief and well-written account of his life will enable future generations to learn what manner of man he was, and will be treasured by all who had the privilege of knowing him. It should also be widely read by aspiring young men in every branch of medical and scientific life as a stimulating example of how this great man, by seizing the opportunities of general practice in a distant land, was able to take an important share in building up the great temple of medical science.

### TRAQUAIR'S PERIMETRY

SOME thirty years ago the study of the normal and abnormal visual fields was raised to the level of a quantitative and exact science—exact as far as subjective clinical methods go—by Bjerrum, and his teaching and methods have been elaborated and brought to a high level of perfection by his follower and disciple Roenne. The exact and differential methods of the Contraental writers were introduced to English-speaking ophthalmologists by Berry in 1890, and the painstaking and intensive researches of Dr TRAQUAIR of Edinburgh, which have now extended over many years, have established him in a unique position of authority in this country to-day as their foremost exponent. His work has been fittingly recognized in the bestowal upon him of the Middlemore Prize in 1920 and the Edward Nettleship Medal in 1922, and it is now gathered together and presented in readily accessible form in *An Introduction to Clinical Perimetry*.

An adequate appreciation of the charting of the visual fields can only be arrived at when its quantitative variations are explored not from the standpoint of vision itself, but from that of the degree of visual acuity. The field may well be compared to an island of vision in a sea of blindness, and the endeavour of the modern perimetrist is not merely to chart out the coastline by rough and ready methods, but to make a complete orographical survey of the whole area with the differences in level shown by contour lines and with all the depressions marked to explore the valleys of small visual acuity and trace their mergence into the plateaux where definition is greatest, to follow out the regions where the finer differentiation of colour is possible, and to demark the regions where blank spaces exist, whether they be erosions upon the coastline (as it were) or inland lakes. In comparison with this which may be termed the technical side of perimetry, the interpretation of these findings is no less important. The aim is to discover and distinguish the various forms of deviation from normal vision, and to correlate as far as possible each alteration with a definite anatomical site of interference in the visual pathway and with a definite causation. Thus in the study of disordered vision the perimetrist is the aesthesiometer of the second nerve and its central organization, and its use in its fullest sense is indispensable, not only to the ophthalmologist, but also, and pre-eminently so, to the neurologist and the intra-cranial surgeon.

In his book Traquair deals with the clinical aspects of the method, and only refers to the more academic questions associated with the physiology and neurology of the vision response in as far as their introduction is necessary to elucidate the clinical findings. The first part of the book deals with the normal field of vision and gives an outline of the characters and the use of the standard instruments. Simplicity in the instrument and simplicity in the technique are insisted upon. The difficulties of perimetry are subjective and psychical, it can never aspire to objective

exactitude. While an elaboration of refinement in apparatus and method may be of value in special circumstances, their use for clinical purposes must be allied with a due sense of perspective for "simple tools" properly used are much to be preferred to "elaborate" ones which induce reliance on the data of an elaborate instrument.

The second part of the book is devoted to the various pathological alterations and defects in the visual field, and to the interpretation of the changes in the retinal lesions in the eye, the visual pathway and the cerebral cortex. The types of defect met with clinically are described and their anatomical and pathological significance pointed out. Each region of the visual tract is then dealt with seriatim: the choroid, the retina, the optic nerve, the chiasm, the optic tracts, the geniculate bodies and the geniculo-calcarine pathway, special attention is paid to glaucoma, and there is a final chapter on functional changes. Changes in the field are interpreted on an anatomical basis, and the various etiological factors causing them are dealt with in detail. Henschen's views are largely followed with regard to the neurological anatomy and controversial points are only lightly touched upon.

Throughout the teaching is sound and the book maintains a high standard of excellence; moreover, it has the merit of personalty and individualism, representing as it does the life work of the author and an immense amount of time and labour spent on accurate clinical observation. The bibliography appended is also valuable. Here and there, however, the argument tends to be diffuse but although it might have been curtailed it always makes pleasant reading. It is luxuriously produced and extremely well printed and illustrated, unfortunately its price is correspondingly luxurious.

### THE NEW HAEMATOLOGY

THE success of the "Recent Advances Series" brought out by Messrs J and A Churchill will be more than maintained by Dr A PRYER's *Recent Advances in Haematology*, which in a comparatively small space contains a large amount of new material, fresh ideas and thought-stimulating suggestions clearly set out. Dr Pryer, whose recent output of work is remarkable and whose industry in keeping abreast with haematological publications is obvious from this book and especially from the appendix briefly summarizing those in his private library, has unobtrusively indicated his own view and thus added a personal interest to a thoroughly up-to-date review which original workers cannot fail to find most helpful.

The reticulo-endothelial system and its relations to the blood diseases are fully discussed and interesting descriptions are given of Gaucher's phenomenon and of the Niemann-Pick disease recently paraded from it. Splenic anaemia is, of course dealt with and attention is drawn to Gamma's disease or splenogranulomatous siderosis. In the account of lymphadenoma reason is brought forward in favour of the view that it is a reticulo-endothelial disease. The origin of solid endonemas from the reticulo-endothelial system is shown by the author to rest on the demonstration of intracellular fibrin in the cells. The ever shifting hypotheses concerning leukaemia and pernicious anaemia are considered in the light of the new data regarded as truly neoplastic in origin, but the possible relation of leukaemia to pernicious anaemia is regarded by Ellermann as still a not really settled. The importance attached to a high percentage of Addisonian anaemia is criticized and it is suggested that the percentage of reticulocytes is a more reliable factor to enable a more precise estimate to be made of the degree of anaemia. Such a suggestion is quite reasonable and it is to be hoped that the present work of the author will be followed by a series of papers to enable a more precise estimate to be made of the degree of anaemia.

The clinical features and the treatment of the blood diseases are succinctly and clearly dealt with in a haematological dictionary. The book is a valuable addition to the literature of the subject and it is to be hoped that it will receive from the medical community the recognition it so thoroughly deserves.

## DEMENTIA PRAECOX

Dr. GABRIEL LANGFELDT, assistant physician at Neerengaarden Asylum, Bergen, records the results of his clinical and experimental investigations of forty unmistakable cases of dementia praecox in a monograph entitled *The Endocrine Glands and Autonomic Systems in Dementia Praecox*.<sup>1</sup> The author set himself two problems to examine: the first, whether the hypothesis of dementia praecox as an endocrine disease was sufficiently supported, and the second, whether there was a distinct difference in somatic respects between the two main types of dementia praecox—katatonia and hebephrenia. Each case was examined by exactly the same methods, which were clinical observations in general (measurements of testes and radiological examinations of sella turcica, thymus, and epiphyseal lines), determination of blood picture, basal metabolism, and effect of endocrine extracts upon physiologically changed basal metabolism, examination of the carbohydrate metabolism, examination of the visceral nervous system.

The characteristics found by the author for the two groups are summarized by him as follows: in katatonia the essential disturbances, present in both acute and quiescent cases, were slow pulse, low blood pressure, lymphocytosis, glandular swelling, positive pilocarpine and Aschner tests (vagotonic signs), and reduced basal metabolism. In acute cases he observed, in addition, certain sympathetic signs such as dilated pupils, tachycardia, exophthalmos, and reduced glucose tolerance. In hebephrenia, in its acute as well as chronic phases, only sympathetic symptoms were observed—tachycardia, tremor, dilated pupils, and reduced glucose tolerance. These symptoms were found most pronounced in acute phases, and only in one was there increased basal metabolism.

These results are made the subject of an interesting discussion, and in concluding his observations the author remarks how important it would be if the somatic symptoms of dementia praecox could be demonstrated at such early stages that they could be applied to forensic psychiatry. It would certainly be useful from the standpoint of prophylaxis if we were able to apply biological tests which would reveal the existence of a psychopathic constitution before morbid symptoms had made their appearance—something analogous to the Schick test for susceptibility to diphtheria. As Rollston has suggested (*BRITISH MEDICAL JOURNAL*, 1925, ii, 782) we feel, however, that the legal mind would be reluctant to recognize any such biological test as affording evidence of responsibility for a delinquency, especially if the offender had exhibited no evident psychic peculiarities at or before the time of the offence.

## EXPERIMENTAL PHARMACOLOGY

HEFFTER's handbook of experimental pharmacology<sup>2</sup> is slowly approaching completion, for the first half of the third and last volume has now appeared. The preparation of this work has been greatly hindered by the sad circumstance of the death of the original editor, and of no fewer than seven of the original contributors.

The section under review deals chiefly with the pharmacological actions of various inorganic substances, and contains articles upon osmotic pressure, action of saline purgatives, action of acids and alkalis, and action of the alkalis and alkaline earths.

The general subject of the action of non-toxic ions on the functions of protoplasm is a field common to physiology, physical chemistry, and pharmacology. The subject is one of particular difficulty, but it is very clearly treated in this volume. The article by Professor R. Hober on the alkalis and alkaline earths is of special value because the author has a wide and fundamental knowledge of the subject.

Professor Buigi of Berne contributes an interesting summary of the action of iodine. The relation between iodine supply and thyroid disorder is dealt with very thoroughly.

<sup>1</sup> *The Endocrine Glands and Autonomic Systems* By Gabriel Langfeldt, Bergen. J. W. Eides L. Co. Ltd. 1926. (52 x 9 pp. 326, 7s. 6c.)

<sup>2</sup> *Handbuch der experimentellen Pharmakologie* By A. Heffter, fortgeführt von W. Heubner. Herausgegeben von H. K. Lewis and Berlin. J. Springer 1927. (Sup. roy. 8vo, pp. vii + 619, 62 figures, 12s. 6d.)

The history of this subject is of particular interest. A full account is given of the wonderful pioneer work of Clinton, who in 1850 stated that endemic thyroid disease was due to deficiency of iodides, and it is interesting to learn that prophylactic administration of iodides was tried in France in 1860. This subject has, of course, aroused much interest in recent years, and great credit is due to the workers who have succeeded in establishing the value of iodine prophylaxis, but it is the same time equal credit must be given to the older workers who arrived at similar conclusions long before it was known that the thyroid excretion contained iodine, or, indeed, before anything was known regarding the functions of the gland. The account given of the history of iodide metabolism is particularly full and is well up to date, as is evidenced by the fact that mention is made of the recent work of Huntington and Bruger on thyroxine.

The enormous subject of the pharmacological action of compounds of arsenic and antimony is dealt with somewhat briefly in articles written by the late Professor Heffter and revised by Professor Keffer. Amongst the other articles mention may be made of one by Professor Rost on the very vexed question of the pharmacology of boric acid. He gives a full account of the researches carried out in Berlin by himself and others on this subject, but fails to provide a critical discussion of the work done in other countries. Though such a discussion would have been best with obvious difficulties, it ought to have been undertaken in a book of this character and magnitude.

In general it may, however, be said that this section maintains the high reputation the book already has established, the hope may be expressed that it will not be long before the publication of the final section, and that this will contain that all important feature—a good general index.

## NOTES ON BOOKS

IN his book on cyclic vomiting accompanied by ketonuria,<sup>3</sup> which has now deservedly reached a second edition, Professor A. B. MARION, from his wealth of experience, describes in detail this well known condition. The interesting question of its etiology is fully discussed: the victims, usually from 2 to 6 years of age, come of the neuroarthritic diathesis, and in adult life are prone to migraine, hepatic disorder, and diabetes; the attacks are favoured by a fatty diet and residence at a high altitude. A sudden disorder of metabolism leads to the formation at the same time of a poison which causes vomiting and of ketone bodies in excess, emphasis is laid on the early appearance of ketonuria, and the suggestion that it is secondary to vomiting and emulsion is firmly controverted, as is also the view that the condition is due to appendicitis. Other explanations, such as nephritis and hepatic insufficiency, are also considered cyclic vomiting being critically compared with delayed chloroform poisoning. In the section on treatment alkalis and avoidance of a fatty diet are recommended, and the rapid curative effect of insulin in the attacks is mentioned.

In *Education for Life: The Training of the Girl Worker* Madame JULIE EVE VÁJNÁK, administrator in Hungary of the Save the Children Fund, has provided an attractive account of the work schools in Hungary, especially of that in the Maria Valéria Huts at Budapest, and asks for subscriptions. Children are not admitted until they have passed the obligatory age limit of the ordinary school, which in Hungary is 12 years of age. Their education, or preparation in the work schools for their future in the factory, has a broad outlook, and has been arranged on a sound psychological basis. This system, though started a few years ago only, has been so successful that the public authorities are taking the schools over, and the girls are so improved in appearance, taste, and efficiency that many of them get married.

Meick's Annual Report 1927, second part, contains a considerable amount of interesting information. An article by Buins on myklostomiasis gives a clear description of this scourge which afflicts so large a proportion of humanity; the author estimates that 500 million individuals are infected. Details are given of the preventive measures by means of which the disease has been practically stamped out in the coalfields, in 1903 about 10 per cent. of the 180,000 miners were infected. The *Lesements Périodiques de la Société de Médecine* Par A. P. Marion. 2e édition. (Paris, 1927.) *Education for Life: The Training of the Girl Worker* By Julie F. Vajnak, administrator in Hungary of the Save the Children Fund with a foreword by Ethel Sigmund. London: The War Child. 1927. (Cr. 8vo, pp. v + 18, 2 plates.)

were infected, whereas to-day much less than 0.1 per cent. is infected. This is a very remarkable triumph for preventive medicine. Much of the book is occupied by short summaries of recent literature regarding various new drugs and new methods of treatment.

## PREPARATIONS AND APPLIANCES

[illegible]

Inti, no nome e Seren

Wellcome has announced that its new Type 1 anti-toxin serum for use in the treatment of pneumonia. Laboratory tests have shown that 0.2 c.c. of this serum will protect a non-vaccinated 100,000 fatal dose of a culture of pneumococcus Type 1. It is therefore hoped that the serum will give favourable clinical results.

4 Simplified Ophthalmic case

Mr. L. L. Farquharson, medical student in the University of Edinburgh, has devised an ophthalmic scope attachment which fits over the end of an Ever Ready pocket torch (fountain pen type). I consist of a lens with a small sight aperture at the back containing a slit and scale to

## MEDICAL INSURANCE IN GERMANY

The working of the national insurance scheme in Germany is apparently beset with considerable difficulties at the present time. These have been brought out and traced to their cause in a pamphlet recently published by Dr Kurt Finkelnburg, who has devoted four years of study to the subject and to an analysis of the schemes in operation in other countries.

The defects in Germany exposed by the author are partly inherent in the original scheme and partly the result of the progressive increase in expenditure and of the measures adopted to diminish it. Under the first heading are included the relation of the medical man to the insurance committees and to the patient. The economist or of medical benefit is not a it is in this

counts, delegated to a special committee with a strong medical representation the insurance committee are composed of two-thirds workers and one third employers and this fact, combined with the strong class antagonism existing in Germany, has an unfavourable influence on the relations between the committees and the doctors who are regarded by the majority in the light of employers. As regards doctor and patient Dr Finkelnberg has definitely deplores the loss of the old personal relationship under which the interest of the patient was the sole concern. Under national insurance the doctor has to consider on the one hand his patient on the other his committee whose watchword is parsimony. The partial detachment from the interest of the patient became complete later on when the medical man grew to be regarded as practically an official of the committee. Nevertheless, the personal relation still seems to be greatly prized in Germany and the tendency to regard the patient as merely an embodied disease is heartily disliked by a wide circle.

A more long blo difficulty is connected with the expenditure on national insurance which appear to have increased by leaps and bounds. The communities blame the doctors, whose expenditure they point out, increased ninefold during the period 1825-1914. It is admitted that they may have been extravagance on the part of individual doctors but not on their part alone apparently, since the communities administrative expenses increased fourteenfold in the same period. Dr Pinkerath mentions several causes for the increase. In the first place the restraining influence of the private part under the old system has gone and treatment is now free. No deep psychological research was needed, he contend to predict that increased demands on the part of the patient would result they may be quite reasonable, and only about under the old system owing to lack of means. Secondly the doctor being to a large extent relieved from personal responsibility would often be tempted to go beyond what was strictly necessary in treatment or employ methods that entailed unjustifiable expense. Thirdly a considerable increase in expenditure, he says to be attributed to propaganda to campaigns against tubercular syphilis, and cancer to the extension of the scope of insurance, to increased price and to innovations in medical technique and the introduction of new drugs.

The matter chiefly in dispute relates to the means adopted to diminish the increased expenditure. The most obvious expedient so far as the medical man is concerned was to limit as far as to a certain fixed maximum and as a general rule to deny a percentage of the revenue of the committee was adopted. This was satisfactory enough in favourable times but in period of financial stress the result has been very much the contrary. Another method was to establish direct control over the doctors either by a committee of medical men or by some leading medical men or superintendents acting as representative of the committee. It is difficult to believe that this plan could work satisfactorily in any circumstances it must be a humiliating position for a doctor to be liable at any moment to have his diagnosis and treatment called in question by an outsider, and the more so in appeal to a higher authority is provided for.

Dr Finkenrath suggests that the first step in reform should be a statutory limitation of the demands of the patient. Insurance in Germany entitles a patient to all "necessary" treatment but what precisely may be considered necessary is a financial matter of dispute between patient, doctors, and committees. no distinction is made between ordinary and special treatment. In these circumstances the remuneration of the doctors must in many instances be fairly inadequate. German doctors evidently have reason to complain.

If it is possible to have opinions on the subject, it would seem that it might be considered in the direction of establishing, on part of the Government, the independence of the medical men, conferring the right of appeal to the Ministry of Health in matters of dispute, bringing the amount of medical fees into relation with the services demanded and defining more clearly the scope of national insurance.

## LIFE ASSURANCE AND PERIODIC HEALTH EXAMINATION

THREE recent books, originating respectively in South Africa,<sup>1</sup> America,<sup>2</sup> and India,<sup>3</sup> and all making contact with life assurance at various angles, serve to mark its steady growth throughout the world, and suggest reflections upon the influence of medicine within this sphere. In the early days of life assurance in London the proposer was inspected by the lay directors of the company, and accepted or rejected on his aspect alone. Later, an experienced medical practitioner was appointed to do the inspecting through professional glasses, but without examination. Later again, with the advance of scientific attainment this rough-and-ready choice gave place to a more or less thorough examination—a vogue which still holds the field. But it no longer holds it unopposed, for twenty five years ago came the bold innovation of assurance without medical examination to challenge our professional complacency, and did it to some purpose. We need not blune ourselves, having acted in good faith, but there is no doubt that we were to some extent misled by our own discoveries, as many a man now living can testify who, twenty, thirty, or forty years ago, was declined for some abnormality—albuminuria, cosuria or heart murmur—which proved harmless. We are wiser now, and have lived to see the medical and the non-medical appraisements coexisting amicably enough, as indeed they ought, being mutually complementary systems. But it is not to be supposed that the success of non-medical insurance under appropriate safeguards, which has been won in London by those who have had wit enough to master its limitations, has enhanced the influence of medical opinion in the life assurance world at home. Things seem to be otherwise in the United States, and probably in South Africa also, if we may judge by the preface of Dr. Paterson MacLaren's sincerely written and laborious book. Who that has been faced with the intricacies of an American medical report for life assurance can doubt that what claims so much in labour must feel assured of an equal claim upon consideration? Besides, not only is medical aid invoked in America for the meticulous selection of candidates, but also for the gracious office of keeping those candidates alive (and in full enjoyment of the privilege of paying regular premiums) by dint of periodic health examinations.

There is probably no department of our professional activities which exhibits more variation in method than the medical examination for life insurance, as appears from a comparison of the questionnaires in use by the various companies. At one end of the scale we

find lists, especially the American which are truly portentous in their extent and particularity, and bid fair to exhaust, not only the subject, but examiner and examinee as well. No crevice of family history or medical past is left unexplored, no clunk or cranny in the physical present escapes the probe, and the luckless applicant (were he fully aware of the inquisition which threatens him) might be forgiven for throwing up his hands and leaving the quest of life insurance to those dauntless souls who are cast by Nature for perilous pursuits. At the other extreme are the societies which seem able to achieve their aims with a far less forbidding display of ink and curiosity, features which at this end of the scale present themselves in diminishing abundance until we reach the zone where approved lives are accepted without medical examination of any kind.

Life insurance, being a trade in a commodity, may be expected to be amenable to ordinary commercial considerations. Accordingly we should look to see the seller making things as easy for the prospective buyer as it is possible to make them. But since in this case the buyer pays for his purchase on the instalment system—that is, by periodical premiums—it follows that the commodity can only be sold profitably to such purchasers as have an average chance of not defaulting (by way of precocious demise) in the payments they have undertaken to make. Hence the necessity for medical selection and the introduction of difficulties in the buyer's way. For medical examination is a difficulty, and the more searching it is the more likely is it to scare away custom. On the other hand, it gives security and improves the quality of the customers, so to speak, and thus counterbalances its drawbacks more or less. At what precise point of balance these competing interests attain their equilibrium of advantage must remain a matter of opinion, and conflicting notions on the subject will no doubt continue to dictate variations in practice.

As regards the medical examination itself, it is a clinical problem, in its way, and needs for its successful solution that the examiner should concentrate upon the few features which are essential to the exclusion of irrelevance. Thus good sense, clinical faculty, and (for choice, of course) experience are the qualities most needed. Given a good equipment in these particulars the examiner stands above the necessity for guidance as to the points which should claim his attention, and exhaustive schedules of questions are superfluous. So we may find added satisfaction in our relative freedom from the microscopic inquiries scheduled in America by regarding it as a tribute to the general level of clinical good sense to be found among our medical examiners.

We have alluded to the periodic health examination offered to their assured lives by some of the American offices. The subject is dealt with at great length in the volume entitled *How to Make the Periodic Health Examination*, though the work itself is in effect a textbook of practical diagnostics. Considering that there is in essence nothing about the periodic health examination which should distinguish it from the routine examination in daily use by the careful practitioner, we may take leave to doubt whether it needs a rather grandiose textbook to itself. But the subject is important, and has not obtained in this country the attention it deserves. Undoubtedly there are among us to day untold numbers of people who are daily inviting (and acquiring) ill health because in all innocence they are entertaining the elements of disease. One man, for example, accustomed in the heyday of

<sup>1</sup> *Medical Insurance Examination* By J. Paterson MacLaren, M.A. B.Sc., M.P., C.M. London: Baillière Tindall and Cox, 1927 (Demy 8vo, pp. vii + 308, 10s. net). — *How to Make the Periodic Health Examination* By Eugene L. Luman, F.R.C. M.D., and J. Ramser Crawford, M.D. New York: Little W. Ireland, New York, 8vo, pp. 393, 4 dollars. <sup>2</sup> *Pocket Guide to* The Macmillan edition revised and enlarged. Bombay: The Times Press, 1927 (Cr 8vo, pp. ii + 85 + 222).

his strength to so much whisky, beer, meat, and so on, continues his eccentric practices into later middle age without any consciousness that he is taking risks. In his duty in his ignorance with rheumatoid arthritis and all the hazards known and suspected which attend upon orils' pils. And so in other connections good citizens continue to court formidable harms or lack of timely advice. There is force no doubt in the argument that the less a man thinks about his health the better and that *quarta non nocet* is a good idea. Nonetheless the periodic health examination conducted on model lines, is a sane and sensible idea which may in time become popular here. So it behooves us to prepare ourselves to do it simply and sensibly with it when it comes in the guise of a free examination paid for by an interested assurance office or as a precaution self sought by a public that has grown wise—wise enough in short to be willing to pay for insurance of health against avoidable risks as it does already for the insurance of life against the inevitable.

### IF GOLD RUST WHAT SHOULD IRON DO?

The report prepared by the Westminster Survey Group on the housing conditions in the Victoria ward of that city is based on an inquiry apparently made with care into a random selection of houses in the area and is now issued with the object of enlightening public opinion so as to strengthen the hands of those engaged in similar work and prepare the way for remedies.

Victoria ward which includes Chelsea Barracks and Victoria Station is bounded on the west by Flury Street and on the east by Vauxhall Bridge Road. Its dwellings range in descending order of merit from good class houses to poor tenement property and cottages which have survived more spacious days. Too old for remodelling, but not yet decrepit enough for demolition, the tenement houses examined showed in general a low state of repair and were invaded by damp from roof and ground and through defects in their walls. Cottages—types of *rue de urbe*—were found with no water laid on indoors. Dark and dangerous staircases, broken fixtures, saturated ceilings, falling plaster, damp basements, absence of refuse bins, and presence of bugs and insects made many houses undesirable or unfit to live in. The number of dirty and careless tenants is said to be surprisingly small and the frequency of damp is adduced as suggesting that omission or neglect of repair by land lords is the principal factor responsible.

The reports were impressed by the abundance of rats in the properties visited. Children are terrified of the rats and refuse to go to bed. In one house the rats gnawed through a new bond in twenty-four hours. In another the tenant keeps a dog for his protection against them. There are however instances.

The existence of overcrowding seems indubitable. Many figures are quoted. The demolition of Walls Yard now happily achieved shows the kind of difficulties which arise. A number of the displaced families have crowded into houses already full and so helped to bring about a return to slum conditions. The recent tendency in Westminster to merge industrial and commercial property at the expense of housing is deplored, and the statement is made and seems incontrovertible that every site so lost for residential purposes is a definite aggravation of the existing evil.

The report points out the administrative and other measures which may be adopted to right what is

wrong. It indicates the steps the citizen may take to set the machine of local government in motion. Being a mission document it does not enlarge on things already being done. It is therefore proper to say that in the annual report of the medical officer of health for Westminster noted on page 279 of this issue a section is devoted to a discussion of the housing schemes of the city. The council would perhaps have displayed a more progressive attitude if they had not reduced the baths in their Willow Street scheme, although a number of bathrooms will be included.

The survey group appear to have made out their case that the housing in the Victoria ward of Westminster is defective and calls for remedy. On the hygiene side it is inhuman. On the social side owing to its degrading influence on family life it reveals an equally serious position. It is not claimed by the survey group that conditions similar to those in Westminster do not exist in other areas but they say that the city of Westminster, with its rating resources, could do more than most to cure the evil and could do it more quickly.

A reader perusing this interesting document with a detached mind receives the impression that defective housing not only exists in Westminster but it has added significance from its setting. Westminster age long has been the heart of England. It may never be regarded as the nucleus of the Empire. It or all cities should be above reproach. It should take the lead and set the pace in this vital matter. If the city of Westminster will not do right what can be expected of other authorities less favoured by tradition and a historic name and less in the public eye? The article quoted as a title above written long ago by the author of the *Canterbury Tales*—a Londoner born and one moreover who knew his Westminster well—is commended at this juncture to the city council for its guidance and inspiration.

### MAJOR GENERAL LEONARD WOOD

MAJOR GENERAL LEONARD WOOD who after a adventurous military career in the service of the United States was appointed governor of the Philippine Islands six years ago died in a Boston nursing home of an operation on the skull on August 10. He was the son of a doctor came of pure New England stock and was born at Winchester, New Hampshire on October 6, 1850. He was a wheel student at Harvard at Harvard in 1868 and entered the army as contract surgeon in the following year. He also immediately saw action in Armenia then hurried by the terrible April of the time when the army and the General Miles was entering on the Indian campaign for the overthrow of Geronimo and his followers. Though there was not much fighting it was an exceedingly dangerous type. It was carried on in the mountainous New Mexico and northern regions of old Mexico in conditions of great physical hardship. Wood was of iron constitution and broad-chested was able to withstand more than most whites whether Indians or frontiersmen and could not be beaten even by the friendly Indian tribes themselves. By the end of the campaign Wood was rated as a commanding officer of a team of foot soldiers and was for particularly arduous and dangerous work and for courage and enterprise won that coveted and of distinction the Medal of Honour. In 1875 he was given an appointment at Washington where he became a friend of Roosevelt, and when war broke out with Spain in 1898 they were together authorized to raise and equip a regiment of volunteer cavalry or rough riders. Wood again distinguished himself by his courage and endurance, as well

as by his abilities, and having been promoted brigadier-general was, on the capture of Santiago, made military governor of that city, which was in a terrible state of anarchy and disorder. Less than four years afterwards he was appointed governor-general of Cuba, and was promoted to be major-general. During his term of office he gave his cordial support to the experiments of Carlos Finlay, Walter Reed, and their colleagues, which made it possible to extirpate yellow fever. In an address Major-General Wood gave in Philadelphia at the end of 1912, he described the reorganization of the government of the island, and said that when the Cuban Republic was set up the government of the island was transferred as a going concern. All the public offices were filled with competent well trained men, its finances had been put in order, completely equipped buildings for the transaction of public business had been provided, and the people were governed in all municipalities by officials of their own choice. Sanitary conditions had been made better than those existing in some parts of the United States, yellow fever had been eradicated, the island was well supplied with hospitals and asylums, and a modern system of education had been introduced, including a university. Very shortly after his return from Cuba President Roosevelt appointed Wood military governor of the Moro Province in the Philippines, and after a tour round the world, during which he made the acquaintance of Lord Roberts in this country and of Lord Cromer in Egypt, and visited India and Java to study administration, he began his work among the Moro tribes, who were pirates by tradition and who lived in open defiance of the government. By 1905 he had pacified the province, which he handed over to his successor possessed of a strong government. After holding the Philippines command for three years, Wood, in 1908, was appointed G.O.C. the United States Department of the East, and after a diplomatic mission to the Argentine was in 1910 appointed Chief of the General Staff. He set to work to impress on his countrymen the necessity, having regard to the position both in America and Europe, of being prepared for war. He succeeded in establishing "volunt officers' training camps, and in the early years of

European war formed several others, so that by 1916 there were six, with an attendance of over 16,000 cadets. It was by these camps that the United States of America were prepared to raise an army of nearly four millions, officered by over 200,000 ex-students of the camps Wood had established. Some thought that when the United States army took the field in France Wood ought to have been commander-in-chief, but party politics intervened, and he was not sent to France until 1917, and then only as an observer. In January, 1918, he was wounded by a fragment of shell, when he recovered he returned to Washington to advise the Military Committee that America should prepare to mobilize an army of five million men. In 1920 he was nominated as a candidate for the Republican Party as President, but he had to give way to Mr. Harding, who, however, as soon as he came into office, sent Wood to the Philippines to investigate the conditions there and to report upon the fitness of the people for independence. A year later he was appointed governor-general of the Philippines, where he had to deal with a strong agitation for independent status. Wood firmly maintained the principle that the essential step was to educate the Filipino people in the principles of popular democratic government, and to give them gradually more share in administration. He held strongly, however, that American sovereignty should be retained, and this was the opinion he expressed when he returned home a short time ago. His death removes a man of strong character and independent views, who, had his life been spared, might have rendered yet other great services to his country.

#### AN OUTBREAK OF FOOD POISONING

We are indebted to Dr. James F. Blackett (M.O.H., Bath) for some particulars of the outbreak of food poisoning which, as has been extensively reported in the daily press, occurred at the end of last week in Bath and some neighbouring districts. He informs us that during the week-end, more particularly on Sunday, August 7th, the medical men practising in certain areas in Bath and to the west of it received a very large number of calls to see patients suffering from gastro-intestinal disturbance. It soon became evident that in practically every case the patient had partaken, on Friday evening, of ice cream from a particular dealer, who travels through the districts affected with a motor cycle and sidecar. This dealer lives at Koyngsham, the area affected consists of that place (a market town of nearly 4,000 inhabitants, about seven miles west of Bath), the western portion of the city of Bath, and certain intermediate villages. The rough estimate of from 200 to 250 cases made by the daily papers is probably approximately correct. Of these, perhaps 50 occurred in the city of Bath. There has been one death (in the city of Bath), but many patients have had severe attacks. Though most of the cases occurred in connexion with Friday night's supply of ice cream, the dealer, ignorant of what was happening, also did his usual round on Saturday, and a certain number of later cases are definitely attributed to ices sold on that day. The attacks varied very little in their clinical nature, except in intensity. Inquiries showed that there had usually been an initial rigor, coming on within twelve hours of eating the ice cream. This was followed by profuse and persistent diarrhoea, associated in the earlier stages with vomiting. The temperature was raised and the pulse rate very rapid. Most of the patients seemed drowsy, but there was no definite evidence of paralysis or changes in the reflexes. The dealer, who has made and sold ice cream for many years, is reported in the press to have stated that the ingredients used were Grade A milk, new laid eggs, corn-flour of a well known brand, and vanilla flavouring. He pointed out, what is certainly true, that a number of persons had consumed ice cream from the same supply and had not been ill. It is understood that a sample of the ice cream made on Saturday is being examined, and that investigations are also being made of material obtained from the patients. The results of the investigations have not yet been made known.

#### ANTIVIVISECTION LETTER WRITERS

SOME five-and-twenty years ago, perhaps earlier, a favourite stunt of the antivivisectionist was to write to rising young medical men—rising in the big national world or in the life of a country town not less important to them at the moment—to ask whether they were sound on vivisection, that is to say, in disapproving it, because the writer knew of someone who would like to consult them but would not be allowed by her conscience to do so if they were shaky. From a spirited letter by Sir Alfred Rice-Oxley, published in the Times of August 9th, it would appear that the plan has been revived, he states that he has received a number of communications from antivivisectionists inquiring if his name may be included among those physicians and surgeons who discountenance vivisection, and informing him that there are many people who desire to consult only those members of the medical faculty who dissociate themselves from what is called vivisection. Thus he interprets to mean that if a practitioner should happen to be in favour of experiments on animals, and if he does not change his views, they will not consult him, and, presumably, will endeavour to persuade other people not to consult him. He expresses the view, which he thinks (as do we) will be shared by most fair-minded people, that

governing organization of nurses only." The pamphlet, which can be obtained (price 3d) from the offices of the Labour party, 33, Fecleston Square, London, S.W.1 is a study of study. We believe it to be true that in the past nurses have often been treated by institutions which employed them with insufficient consideration, and that there is still need for improvement. At the same time we must not be taken as agreeing to the proposition that the Labour party's practice of a trade union is well applicable to them calling

#### MACALISTER MEMORIAL AT ROYAL SOCIETY OF MEDICINE

A new episcopo has been installed at the Royal Society of Medicine as part of the memorial to the late secretary, Sir John MacAlister. The instrument has been constructed in Germany by Carl Zeiss according to the specifications of the committee in charge of the memorial, on whose behalf the secretary of the society (Mr. G. R. Edwards), accompanied by the operator, made a special journey to Jena and spent four days in the Zeiss workshops conferring with experts of the firm. The instrument offers excellent facilities for projection, and images of solid objects, such as books or bottled specimens, highly illuminated, are thrown on the screen with great clearness. It has two optical benches, both served by a 10 ampere a.c. lamp, one of them fitted for the purpose of microscopical projection over a great range of diameters, and the other for the projection of all kinds of lantern slides and photographs up to the largest ordinary plate or film size of 10 in. by 12 in. The working of the instrument is very smooth so that it is possible to change from one type of projection to another without any disturbing hiatus. Another device is a dimmer, whereby the lights in the hall are slowly extinguished, thus avoiding the ocular strain consequent upon abrupt transition from light to darkness. The whole instrument is mounted on a suitable platform, and a plate on the front records the fact that it is part of the memorial subscribed by the Fellows of the society to the late secretary.

#### PARATHYROID HORMONE AND CALCIUM ABSORPTION

The measurement of calcium output and intake by the animal body has always presented a very difficult problem to those working on calcium metabolism. The difficulty is due to the fact that calcium is excreted both by the kidney and by the large intestine, while, if conditions are favourable, it is absorbed in the upper part of the bowel. When the calcium content of the faeces, therefore, has been determined, it still remains to be decided how much of that calcium represents excretion and how much is merely material which has passed along the alimentary canal without being absorbed. The determination of "calcium balance" is on this account a matter of difficulty. Stewart and Percival endeavoured to determine the source of the extra calcium that finds its way into the blood as a result of the administration of Collip's parathyroid extract. They solved the difficulty presented by intestinal absorption and excretion by using anesthetized animals from which the whole alimentary canal was removed. They had previously ascertained that anesthesia did not interfere with the rise of blood calcium caused by the injection of the extract. In the conditions of their experiment, had the rise in blood calcium been due to increased absorption it would have been prevented, if it had been caused by diminished excretion it must have occurred without administration of the hormone. As it was the blood calcium remained stationary until the extract was given, after which it showed a rise quite comparable to that found in the intact animal. Absorption and excretion, therefore, play no part

in the phenomenon. The extra calcium may come from either the soft tissues or the bones, a question which can only be definitely decided by further inquiry. There is some evidence which points to its ultimate source in the bones, but the soft tissues may very likely form a more immediate calcium reservoir.

In the list of birthday honours published in our issue of June 11th the distinction of C.B.E. (Civil), conferred upon Dr. Gustav Weber Thompson, medical officer of health to the Jamaican Mines Board of Health, Bihari and Orissa, was omitted, the official announcement did not indicate that the recipient was a member of the medical profession.

#### THE NEUROLOGICAL CONFERENCE IN LONDON

The conference in London last week of the American Neurological Association and the Section of Neurology of the Royal Society of Medicine held two discussions, one on the cerebellum and the other on sensory disorders in organic disease of the nervous system.

##### *The Cerebellum*

The discussion on the cerebellum was opened on Wednesday, July 27th, by Dr. H. A. Remy (New York) in a most illuminating communication. He gave the results of investigations carried out in conjunction with Dr. Frederick Tilney of New York on the comparative morphology of the cerebellum. He showed charts and models of the inferior olives and their connexions and of the lateral expansions of the cerebellum in the primate series. By these and lantern slides he demonstrated a correlation between the arbor vitae and the folial pattern on the one hand and the physical form of the various animals studied on the other. For example in the sloth, with its specialized and simple arboreal activities, there was an arbor vitae without lateral expansions, whilst in the elephant both arbor vitae and folial patterns were very complicated. Of the animals studied rodents and bats possessed the smallest cerebellum, but its structure was by no means simple. He believed that the development of lobulus C in primates is related with the greater independence of the fore-limbs. It was, he considered, unnecessary to recognize a middle lobe, a division into anterior and posterior lobes being sufficient. His studies indicated that the most cephalic and caudal portions of the vermis are least modified in primates. Development of certain parts of the cerebellum could be related with peculiar activities characterizing each animal group. Thus, in aquatic mammals, lobulus parafloccularis was prominent. No definite statement could be made as to the functional localization in all the lobules in man. Lobulus 4 and lobulus C with their hemispherical expansions showed the greatest progressive differentiation in the primate series. This was probably due, he thought, to the result of the perfection of skilled movements and the unilateral independence of the fore-limbs and hind-limbs. He was hopeful that further investigation on comparative morphology would further illuminate the study of functional localization in the cerebellum.

Dr. Porro (Chicago) who has been working in conjunction with Dr. L. Davis on the physiology of the cerebellum, gave an epitome of their results on reflex patterns in decerebrate animals, with and without the cerebellum. They stated that by ligation of the basilar artery in front of the inferior cerebellar arteries, followed by ligation of both carotids, ideal decerebrate preparations could be obtained. By cutting out, in addition, the inferior cerebellar supply the cerebellum was rendered functionless. They claimed that one advantage of this method is that the temperature of the animal does not tend to fall so rapidly as in the Sherrington preparation produced by transection of the mid-brain.

Dr. MESSERS (Baltimore) described certain experimental results, many of which are so revolutionary that confirmation will be necessary before they can be accepted. For example, he described various movements obtained by bipolar electric stimulation of different parts of the cerebellum, results that are opposed to all previous observations.

Dr. FRANK STERN (Philadelphia) dealt with the surgical aspect of the problem, and Dr. L. H. WITKOWSKA with the clinical results of cerebellar lesions. The latter rightly criticized the diversity of the nomenclature used to describe the various phenomena and pleaded for more coherence in this respect. Lesions of the cerebellum resulted in disorders of movement and attitude which were extremely difficult to describe from clinical observation alone, but could be better analysed in kinesthetic pictures which he had used extensively in his investigation. On the basis of disorder resulting from focal lesions of the cerebellum, he had been led finally to believe in functional localization in this part of the brain. These conclusions were described along with many interesting observations on cerebellar disorders in a whole.

Dr. LUCIEN BERNI gave an account of her investigation on disorders of the vocal cords following cerebellar lesions. She concluded that dysplasia of cerebellar origin results in lesions which involve not only the cerebellum itself but also the tracts which connect it with the medulla. The discussion was continued by Dr. WALSH, Dr. GORDON HOLMES, and Dr. KENNETH WILSON.

#### Sensory Disorders in Organic Disease of the Nervous System

At the beginning of the meeting on Thursday it was unanimously agreed to send a message of sympathy and appreciation to Sir Henry Head whose clinical contributions on this subject form so much of the basis of our present knowledge.

Professor J. S. B. STOFFORD introduced the discussion on sensory disturbances following division and suture of a peripheral nerve. His experiences during the war had led him to accept Head's primary classification of cutaneous sensibility into cutaneous and deep. Cutaneous sensibility, as Head described it, was composed of two systems—namely, epipathic and protopathic—the first discriminative and the second protective in function. Professor Stofford, however, diverged from Head's published views in believing that a similar classification in regard to deep sensibility was possible and in fact, imperative on clinical evidence. The evidence upon which this classification was based by Head in regard to cutaneous sensibility is well known. It depends upon the investigations of sensation in the intermediate zone after injury of a peripheral nerve upon the division the following division of posterior roots in which the intermediate area is sensitive to epipathic but not to protopathic qualities—the opposite condition in other words to that which occurs after lesion of peripheral nerves. The recovery of protopathic before epipathic sensibility after suture of a peripheral nerve, the persistence for an indefinite time of protopathic forms of sensation when regeneration is incomplete, and, finally, the normal absence of protopathic sensibility in the glans penis. According to Professor Stofford, evidence of a similar kind as the result of clinical observation, supported his claim that deep sensibility was also based on two anatomical systems with the same phylogenetic significance. Thus, after suture of a peripheral nerve, the two-stage process of recovery could be shown to occur: protective elements such as pressure and pressure pain reappearing before epipathic functions such as localization and passive position. So also he found indefinite persistence or the first stage of recovery. Finally, in the glans penis localization in the normal individual is imperfect and increasing pressure gives rise to diffuse pain. He therefore urged that deep sensibility should be brought into line with Head's classification of cutaneous sensibility. He suggested that a better classification, based on the clinical facts of recovering sensibility after suture of a peripheral nerve, would be into (1) those elements that recover early, and (2) those that recover late. He went on to compare the two groups of peripheral sensation with thalamic sensibility on the one hand and cortical sensibility

on the other. The phenomena of peripheral "reference," which have never been adequately explained, he believed to be due in the case of recovery after suture, to disturbance of intracranial patterns.

Dr. WILFRED HARRIS gave a description of the sensory disorders which may follow spinal and brain stem lesions. Dr. GORDON HOLMES dealt with the disorders of sensation resulting from lesions of the spinal cord, brain stem and optic thalamus. He recalled the results of investigations by Head and himself which demonstrated that many sensory qualities could be recognized without intervention of the cerebral cortex. The ones they had attributed to the activity of the optic thalamus. But he has since been led to believe that portions of the brain stem are also concerned in the recognition of certain sensory elements. After lesions confined to the cerebral cortex, sensibility to pain to heat and cold was never abolished over the affected area of the body, but in intelligent patients qualitative changes could be demonstrated. It was characteristic of sensory disorders after cortical lesions that hallucinations were frequent and tended to confuse the observer. These abnormalities were described by Head and himself, and consisted of the persistence of a sensation for some time after the removal of the stimulus. This phenomenon Dr. Holmes believed to be due to imperfect cortical inhibition of thalamic and other subcortical sensory "centres", in other words it was a reflex phenomenon. He pleaded for the more common use of the compass test in sensory investigation and illustrated its importance by relating four cases of cerebral lesion in which tactile discrimination was the only sensory quality affected. He recalled Head's classification of sensory function subdivided by the cerebral cortex into three categories—namely, the appreciation of spatial relationships, the power of reacting adequately to stimuli of different intensities, but of the same sensory quality, and the recognition of similarity and difference. Finally, he described his views on the localization of the sensory functions. He believed that the cortex in front of the Rolandic fissure took no direct part in sensation and that the sensory cortex extended backward, from the fissure into the anterior part of the supramarginal gyrus. The posterior part of this region was concerned mainly with the recognition of form, shape, and size, whilst defective postural sensibility resulted from lesion in front of this area.

Dr. KENNETH WILSON's contribution dealt with certain dysaesthetic and thalamic correlations. It had he said long been known that numbness, tingling, pins and needles, and other abnormal sensations were common results of lesions of the nervous system at different anatomical levels. The fact that they were not infrequently associated with vascular disorders had led him to believe that there were two factors in the production of dysaesthesia—namely, nervous and vascular. He gave as an example, the neuropathetic disease common in middle-aged women, and described an interesting case of occlusion of the posterior inferior cerebellar artery in which there were abnormal sensations on the right side of the face and so long as they were experienced by the patient the skin did not bleed when pricked. When the numbness disappeared bleeding could be produced. He urged that this instance was most suggestive of vaso-constriction as a factor in the production of both phenomena. At the thalamic level, painful as well as thermal dysaesthesia might be prominent in the clinical picture. With lesions at the level of the cortex, abnormal sensations such as pins-and-needles and numbness were frequently described as auras to epileptic motor seizures. In one case a patient or severe coldness over the whole of one side of the body complained of. Pain was very rare at this level but Foster has described pain in the region of the head at the onset of a Jacksonian fit. This paper was not suggestive and instructive and illuminated a subject on which too little attention has been paid.

The whole of Tuesday and the afternoon of Wednesday and Thursday were given up to demonstrations and the reading of independent papers. The delivery of the Hughlings Jackson lecture by Dr. Charles L. Dana was noted in the week (p. 225).

## Nova et Vetera.

### ITALY'S CAMPAIGN AGAINST MALARIA

BY  
PROFESSOR ARTURO CASTIGLIONI, M.D.,  
MEMBER OF THE HIGH SANITARY COUNCIL OF THE KINGDOM

FROM ancient times the struggle with malaria has been one of the gravest problems in the lands now comprising the Kingdom of Italy. The archaeologists' excavations show that the Latins attempted to drain the marshes and swamps, looking to this as a means whereby they might exterminate the disease. The Romans also fully realized the peril of malaria infection, and erected temples to the god *Febus*, even to-day their great aqueducts can still be traced, and testify to the grandeur of Rome, whose colonization of the "Campagna Romana" included not only the eradication of the marshlands of the provinces, but thereby made possible the building thereon of flourishing cities and magnificent villas. With the fall of the Roman Empire the population of Italy was sensibly decreased by the devastation of war, disease, and famine, and Rome, now little more than a borough, her culture abandoned, the "Campagna" became again the seat of malaria infection.

In the subsequent renaissance of Italian medicine, however, there were several illustrious members of the profession, as, for instance, Giovanni Maria Lancisi, professor of medicine in the University of Rome (1654-1720), who affirmed that the prevalence of malaria resulted from the unhygienic state of the marshlands. From this time onwards attempts were made to carry on a systematic campaign against the disease. Italy, divided into small states and foreign principalities, was in no position to make a definite attack upon such a serious question, but on the formation of the kingdom, the labours of the great Italian malariologists—Grassi, Celli, Marchesani, Bignami, and others—with the collaboration of foreign students (of whom, in the first line, Ronald Ross shall be named), traced the malaria parasite and the mode by which it was transmitted into the human blood. They inaugurated and founded hygienic legislation based on the gratuitous supply of large quantities of quinine in the malarial regions and on the improvement of the marshlands, these steps producing immediate and favourable results.

From 1887 to 1922 there was an average of 15,000 deaths per annum from malaria. This figure, however, rapidly decreased to an average of about 8,000 deaths per annum between 1903 and 1905. Such decline continued until, in 1914, the number of deaths was little more than 2,000—that is, 57 deaths per million inhabitants. The war years showed a great augmentation, with a maximum of 11,487 deaths in 1918 in which year also a very serious influenza epidemic was responsible for the death of a large number of individuals already weakened by malaria. The subsequent years show a rapid and progressive diminution of malaria, and in 1925 the number was again little more than 3,000—a figure not far off that for 1914.

The regions most sorely stricken by malaria are those in the south of Sardinia and certain Sicilian provinces. Northern Italy influences the statistics most favourably with a proportional average of not more than 10 deaths per 100,000 inhabitants. The observations recently gathered and summarized in an interesting publication of the Board of Public Health show the whole of Italy divided into two large zones, the first of which comprises the whole of Northern Italy and a part of Central Italy. In this zone the malaria is shown to be of a very mild character, with a reduced mortality. The second zone comprises the province of Grosseto and all Southern Italy, where the mortality is very great. The centre of the malaria infection is shown to be found in the island of Sardinia, this being attributable to the special conditions of the locality, which render very difficult the campaign against the disease.

The statistics dealing with the morbidity from malaria also indicate the same rapid diminution in the figures registered by the hospitals and the army.

As already stated the Italian legislature considers one of the principal points of the antimalaria campaign to be the State distribution of quinine. All quinine in Italy is prepared in the State laboratories under the direction of the Minister of Finance, and after an exhaustive scrutiny on the part of the Board of Health is sold to the pharmacists and public retailers. The local authorities, the hospitals, and charitable organizations are empowered to receive the quinine on special conditions at a lower price than that asked from the public sellers, and the poorer local authorities are allowed to have it on credit. All profits arising from the sale of quinine are placed in a special reserve fund.

Another important step towards the diminution of malaria is the classification of this disease as an occupational complaint. By the provision of the law the entire expense of the protection from malaria of the rural population, and of those employed in public works, has to be borne by the landowners or by the contractors, deaths from malaria are therefore considered as a misfortune arising from occupation, and, as such, carrying a right to indemnity.

Other features of Italy's antimalaria legislation provide for a gratuitous supply of quinine and assistance towards sanitation purposes for all workers and settlers inhabiting malarial zones. Mechanical prophylactics are also guaranteed in many infected rivers.

During recent years the Italian Government has introduced a series of new enactments, which are the fruit of twenty years' experience of antimalarial work, they having opened in malarial centres research institutes for purposes of diagnosis, and founded at Nettuno, in the vicinity of Rome, a school of malariology. Further, an antimalarial ambulatorium exists in every district where malaria has occurred, but one of the more important measures for the permanent immunity of the malarial regions has been to render the ill-malarial conditions such as will make impossible the reproduction of anopheles, by draining the marshlands and increasing agricultural cultivation in these parts.

With regard to prophylaxis, for many years scientists have been engaged on plans for the extermination of anopheline mosquitos. These include the poisoning of petioles with oil of heavy oil on the surface of stagnant pools, the introduction of the *Gambusia affinis*, a fish that will devour the larvae and breed very rapidly, and the breeding of cattle in the malarial regions. The latter, however, represents a more important measure, namely, the obtaining of anopheles without malaria—that is to say, mosquitos which no longer sting the human species but prefer other species, mosquitos, in fact, which have taken a dislike to human beings and at the same time have become zoophilic. There are places in Italy where such anopheles have but no longer sting our species, and hence malaria is definitely disappearing, such, for instance, is the district of Schio between Castellana di Stabia and Torre Annunziata. In other places the anopheles sting human beings solely from the spring onwards to July, and hence the malaria takes on a very mild character in these localities, as, for example, at San Rossore, near Pisa.

Another problem which is much more important for Italy, as well as for other lands, such as India, the United States, and the Philippines, is that of the relation between malaria and the cultivation of rice. The study of the subject which has been made in Italy demonstrates that in the places where rice is cultivated the development of anopheles is much more marked. Therefore, from this aspect also research has obtained considerable success. A change in the biological state of malaria—namely, that the insects sting non-human species much more readily than greatly facilitating the campaign against malaria, as their gathering in such places as stables renders their destruction much easier.

The whole of the problem of malaria has been discussed in long debates at the International Conference held at Rome in 1925, and also in other important gatherings, such as the conference of the American National Committee at New Orleans. The particular character, however, of the campaign against malaria in Italy is due to the fact that this campaign is directed on the basis of a special antimalarial legislation conducted under the energetic and

continuous control of the Government with the aid of funds derived in part through the said campaign, a sum of nearly four million lire (£25 000 sterling) being obtained from the State sale of quinine in the course of a year for subsequent employment in subsidies for antimalarial purposes. This campaign, under the wise and energetic guidance of the men who control Italy's public health service, with the co-operation of all her hygienists and physicians and of many institutions such as the Italian Red Cross which has established various colonies for malnourished children, is conducted with the utmost goodwill.

Thus with high hopes of solving this grave problem, modern Italy follows the example of her great masters of hygiene the Romans of old time, aided by energetic legislation and every modern weapon.

## England and Wales.

### TREATMENT OF AFTER-EFFECTS OF ENCEPHALITIS

A CONFERENCE on encephalitis lethargica, summoned by the Minister of Health, was held in London on June 14th, when the Secretary to the Ministry of Health presided, and there were present medical officers of health, representatives of the Ministry of Health, Board of Education, and Board of Control. At the conference the chairman recommended that the procedure adopted in Bristol for dealing with patients suffering from late manifestations of the disease should be carried out throughout the country.

There are in Bristol between 150 and 200 such cases. By arrangement between the medical officers of the Health and Education Committees and the officers of the Board of Guardians these patients have been admitted for the last eighteen months to the Southmead Pool Hospital for long periods. In 1925 thirty-one cases were treated there, of whom eleven were men, thirteen women, and seven children. The numbers for 1926 were about the same. At Southmead these patients are kept under close observation by the medical superintendent, Dr P. Phillips.

The best results have been obtained from open air treatment. The adults sleep on balconies and are encouraged to follow out-of-door pursuits during the day. Terraces in front of the hospital have been made into putting greens. The instillation of fresh air has also given a new interest to many patients and improved their powers of concentration.

The fewest number of refractory cases occur amongst children. They are also kept in the open air as much as possible. They all attend a school in the hospital for three hours daily. Their diet includes fruit and cod liver oil and malt with iron. Ultra-violet irradiation has been given during the winter, but no definite improvement has followed. Laparotomy of the parathyroid glands, to raise in patients with excessive albinism has been tried but the results are disappointing. Massage and remedial exercises are given to both children and adults, the improvement of the physical disability is slow, but the effect on the moral of the patients is excellent. Children suffering from inversion of the diurnal rhythm have been put to sleep in rooms illuminated with various coloured lights, or these blue seems to have the most soothing effect. On the whole, however, this line of treatment is a failure and much better results are obtained from a firm but kindly discipline. Restlessness and sleeplessness are better overcome by obtaining natural fatigue than by the use of drugs—for example, boys who could not sleep at night were encouraged to kick about a football by day until thoroughly tired. Their restlessness soon vanished. Drug treatment both in children and adults is disappointing, and the prognosis of patients with the Pauli mania syndrome is bad.

The encouraging results obtained by the Southmead system have led the public health authorities in Bristol to conclude that the majority of patients suffering from the late effects of encephalitis lethargica are unsuitable for treatment under the Mental Deficiency Act that they benefit most by an out-of-door life under skilled discipline, and that there is ample provision at Southmead for the needs

of such patients at present. The Bristol Health Committee has not felt justified in pressing the Ministry of Health to sanction the provision of special accommodation for patients from the Bristol area. If this plan proves equally successful elsewhere the necessity of building large and expensive institutions for dealing with the disease, as originally proposed, will be obviated.

### HEALTH OF WESTMINSTER

Dr Andrew J. Shinnie, medical officer of health for Westminster, in his annual report for 1926, estimates the civilian population of the city at 141,578. The birth rate for the year was 11.3 as against 17.1 for the County of London, and the death rate was 11.6 the same as that of the county. The infantile mortality rate was 59.7 per 1,000 births. Measles, prevalent during 1926, was on the whole mild, and diphtheria and scarlet fever were less frequent than in the previous year. The Schick test, followed by active immunization against diphtheria, had been carried out in 1925 at the Newport Market Army Training School. In 1926 this work was continued and a beginning was made also, on a community basis, at one of the child welfare centres. During the year the council took over the child welfare activities of the Westminster Health Society in the northern wards of the city, and two new centres were opened elsewhere, one by the council and one by the society. The Regency Street housing scheme was modified to meet the views of the Minister of Health, the change involving some loss of accommodation. Of 77 flats 4 will be two-room, 45 three-room, and 28 four-room. The Willow Street scheme will contain 41 flats and take in 200 people. By the terms of the lease building must be completed by September, 1927, and the council, wishing to make speed, decided to forgo the formalities qualifying for a State subsidy and to meet the cost from revenue. They took the opportunity at the same time to omit baths from some flats "although a number of bath rooms will be included." Seventy-one families since 1925 have accepted vacancies on London County Council housing estates. Many Westminster people, however, cling to Westminster and would be immigrants to it are many. So congestion continues.

### TUBERCULOSIS VILLAGE SETTLEMENTS

The Insurance Committee for the city of Coventry has passed a resolution urging the Government to require local authorities to formulate schemes for village settlements on the lines of the Cambridgeshire Tuberculosis Colony at Papworth. The committee is of opinion that such colonies would stop the leakage in value of tuberculosis schemes, and would seem to assume that the number of workers to be dealt with in this way is comparatively limited. Hence it thinks that such schemes would not be too costly, and that the subsidized work of the colonies would not compete unduly with ordinary industry. Perhaps the time is not yet ripe for being dogmatic in this matter at all events the committee appears to have overlooked the weighty criticism of their proposal involved in the remarks made by Dr F. N. Kay-Menzies in his address to the National Association for the Prevention of Tuberculosis in July, 1924. The Coventry Insurance Committee might be advised to ascertain the number of families in the country requiring transplantation, the accommodation needed, and the cost of such a national scheme, including the new officials who would be required. An experiment in a purely industrial area would be interesting and if the earnings of the inhabitants should prove to fall a little short of complete economic maintenance the financial risks would not be too onerous for local private philanthropy to undertake. We note by the by that the Coventry committee does not differentiate between village settlements and colonies. Some seem to use the former term for a place of permanent residence while reserving the latter for training places used as a stage through which the tuberculous person will pass back to ordinary industrial life.

### TREATMENT OF TUBERCULOSIS BY ARTIFICIAL LIGHT

Very good results have been obtained in Lancashire by the use of artificial light for lupus and adenitis with abscess formation and skin involvement. Of forty-eight

patient with lupus, several of whom had been treated in other ways for many years without much benefit, twenty-one were apparently cured, while twenty-seven still under treatment have been much improved. Similarly, thirty out of thirty-six patients with adenitis became quiescent, three were benefited, and three remained stationary. Dr G. Lassus Cox, central tuberculosis officer to the Lancashire county council, has issued a special report on the treatment of tuberculosis by artificial light in the dispensaries at Lancaster and Ashton-under-Lyne, the former was opened in July, 1925, and the latter two months later. The sources of light employed were the low flame carbon arc and mercury vapour lamps. The average duration of light therapy in lupus was thirteen months, and in adenitis eight months, it is claimed that considerable financial economy has resulted in the treatment of these patients. The total initial outlay on light equipment in Lancaster was £105 and at Ashton-under-Lyne £333, down to the end of 1926 the number of patients treated at Lancaster was thirty-seven and at Ashton-under-Lyne 150. Considerable benefit also followed the use of artificial light in the treatment of tuberculous lesions of the bones and joints, but the few pulmonary cases in which it was employed did not respond well.

#### CITY OF LONDON

In his annual report for 1926 on the health of the City of London Dr Howarth estimates the population at 13,230. The birth rate was 7.1 per 1,000 and the death rate 10.4. The cases of infectious disease notified numbered 105, and all but 22 per cent were removed to hospital. New patients at the tuberculosis dispensary numbered 410. Investigation of the atmospheric pollution of the city continues. During November the total deposit in the city, limited as in area of one square mile, was 73 tons. Over the year the amount of impurity at noon ranged from half a milligram to six milligrams per cubic metre of air. The number of milk samples examined in 1926 was 295, of which all but 12 were up to the 3 per cent standard for fat. Of 42 samples examined for dirt 28 were clean and the rest nearly so. Thirty-four specimens were examined for *B. tuberculosis* and all were found to be free. These are satisfactory figures. The account of the meat inspections at Smithfield contains many points of interest. The quality of the British supplies was good. Inquiries addressed to the owners of tuberculous pig carcasses elicited that the diseased pigs in many cases had never been in contact with cows or cow's milk, a viral infection, contracted from fowls, was probably responsible. Argentine meat was, as usual, nearly perfect, but both Argentine and New Zealand mutton showed an increase of caseous lymphadenitis. A consignment of chilled Australian beef was good in quality, grading and dressing, but many pieces, when unsheated, were found to be affected with mould. Explanations offered by the consigning firm were insufficient pre-cooling of the storage chamber before loading, lack of circulation, excess of moisture in the atmosphere, or opening of the chamber en route. The Alcock electric defrosting process for meat was continued experimentally at Smithfield, but the trade does not favour it on the ground that the meat is burred round the insertion of the electrodes. Fresh meat from Holland was under embargo from May, owing to the discovery of the lesions of foot-and-mouth disease in nasals of pig carcasses imported into Scotland. An increase in the number of live pigs sent by the Irish Free State assisted in supplying the deficiency so occasioned. A problem arose in connexion with the tinned fruit trade. Preserved loganberries in blown or convex-ended tins were found on inspection to be quite good, and sample blown tins were sent for examination to the city bacteriologist and the city analyst. The bacteriologist saw no signs of putrefaction on puncture, found the contents nearly sterile and decided that the convexity of the ends was not due to bacterial action. The analyst observed bubbles of gas on puncture, found the alcohol content up to 0.46 per cent proof spirit, and ascribed the blowing of the tins to alcoholic fermentation. The Ministry of Health was informed of the facts. Rat destruction was carried on continuously throughout the year and the number killed was large. The proofing,

tipping, and other measures adopted mainly strike at *M. norvegicus*, or the brown rat. Its numbers, therefore, are being proportionately more reduced than those of *M. rattus* or the black rat, so that the black rat in the city now outnumbers the brown rat by at least three to one.

#### PLYMOUTH VOLUNTARY HOSPITALS COMMITTEE

The report, recently issued, of the Plymouth Voluntary Hospitals Committee for the year ending September 30th, 1926, affords evidence of much activity. The income from the "1d in the £" contributory scheme has increased by £4,379 to a total of over £16,000 for the year, and the membership of the scheme is 42,000, compared with 14,000 in 1923. The committee does valuable work in inquiring into the hospital accommodation available, and making suggestions for modification or extension. Thus the possibility of amalgamating the South Devon and East Cornwall Hospital and the Bar and Throft Hospital has been considered, questions of additional benefits granted by approved societies to members who were also "1d in the £" contributors have also been discussed. A new method of medical certification for members applying for hospital treatment has been introduced, with, it is hoped, advantage to the working of the contributory scheme.

#### LIGHT TREATMENT AT THE ROYAL FREE HOSPITAL

The Royal Free Hospital was presented by the late Mr Langton with a fully equipped light department, which is attached to the electro-therapeutic department under the care of Dr Hield. In the *Magazine of the London (R.F.H.) School of Medicine for Women* Dr F. Mackenzie Shattock recently published a report on the first year's working of the department. The accommodation is well arranged, a variety of lamps are in use, and 9,562 treatments were given in twelve months. Of the 290 patients treated, 118 are stated to have been cured or much improved, in 88 cases there was slight improvement, and 84 patients were either not improved or became worse. Miss Shattock is content to record the results with very little comment, so that it is not possible to gather the value she attaches to the treatment. Moreover, in diseases in which marked improvement occurred, such as rickets, it is noted that other treatment was used concurrently. Doubtless with extended experience the department will be able to issue more definite reports, in the meantime it has been found that students of the hospital who took occasional doses of light found that it acted as a pleasant stimulant. May we suggest that in future reports Miss Shattock will not write of "patients which" and "cases who"?

#### \* PROPOSED SEVERIFICATION OF MENTAL DEFECTIVES

The paragraph published under this heading in last week's issue (p. 231) was in error in stating that it was the London County Council which had passed a resolution on this subject, the resolution in question was passed by the London Mental Hospitals Committee in the form of a recommendation to the Council, and although it was on the agenda of the Council for July 26th it was not submitted.

## Scotland.

#### NOTIFICATION OF PUERPERAL FEVER

A circular has recently been issued by the Scottish Board of Health dealing with the notification of puerperal fever. The Board states that instances have been brought to notice of failure or delay on the part of medical practitioners to notify to the Public Health Authority cases of puerperal fever in their practice. The Board has impressed on local authorities in Scotland the necessity for making arrangements for treatment under the best hospital conditions, with the use of a theatre or suitable room where operative treatment can be carried out, for adequate safeguards against infection from other diseases, and for the services of a specialist in gynaecology and a resident medical officer. In certain cases where the hospital provision made by a local authority is insufficient,

arrangements have been made for treatment in one of the larger hospitals within reasonable distance. The Board has advised local authorities that, should any instance of failure or delay in notification come under the notice of the medical officer of health, he should report it to the local authority in order that it may consider whether the facts should be reported to the Procurator Fiscal in accordance with Section 5 of the Infectious Diseases (Notification) Act 1887. The Board also intimates that on receipt of particulars of a conviction, the Board will consider whether the case is one that should be brought to the notice of the General Medical Council. Principal morbidity is defined as including all conditions in which the temperature reaches 100° F. on two occasions from the end of the first to the end of the eighth day after delivery.

#### SCOTTISH WESTERN ASYLUMS' RESEARCH INSTITUTE

The seventeenth annual report of work done in the laboratory of the Scottish Western Asylums Research Institute has been issued by the director, Dr William Whitlaw. It is situated in Glasgow, and makes reports for the asylums of the Glasgow district and also conducts research work. Specimens associated with typhoid fever were very much fewer than in the previous year when an outbreak of the disease took place at Dalkeith Asylum. No specimens examined for clinical purposes during the year included 564 of blood for the Wassermann reaction and 135 of cerebrospinal fluid. The laboratory had carried out an estimation of the sodium and potassium contained in cerebrospinal fluid in cases showing convulsive attacks and had estimated also the cholesterol and organic phosphorus contained in similar cases. Cases of tumour of the brain and disseminated sclerosis had also been investigated. 12 cases of general paralysis had been treated by protein shock therapy but only one showed any improvement. The treatment of general paralysis with malaria from infected mosquitoes had been carried out in 33 cases; good remissions had been obtained in 18 per cent of cases treated while all the cases treated showed an improvement in physical health.

#### HEALTH OF GLASGOW

The annual report for 1926 by Dr A. S. M. Macgregor (M.O.H. Glasgow) states the population of the city was estimated at 1,101,622, compared with 1,097,241 for the same area in 1925. The births during the year numbered 24,345 compared with 25,416 in 1925. The birth rate is therefore, 22.10 per 1,000 per annum, as compared with 23.15 in 1925. This is the lowest rate recorded since the war. The total number of deaths registered during the year was 16,156 and the corrected number allowing for transfers was 15,628. The death rate was thus 14.2 per 1,000 compared with 14.0 for the previous year. The death rate due to infectious diseases was 1.25 per 1,000. The most serious infectious disease which had prevailed was measles but its effect on the vital statistics was to some extent balanced by a lower prevalence of whooping-cough. Scarlet fever has been gradually increasing since the war in incidence although not in severity, and the mortality from this disease was 89 per million. The influenza death rate was 330 per million but the incidence of this disease was confined to the late spring when a sudden severe outbreak occurred. The death rate from pulmonary tuberculosis declined still further and had reached the comparatively low figure of 0.66 per 1,000, as compared with 0.82 for 1925 and 1.0 for 1924; the rate was half that of 1915. Enteric fever has become almost negligible as a cause of death. The deaths of infants under 1 year of age numbered 2,532 in 1926 compared with 2,591 in 1925. The death rate per 1,000 births was 164. During the year supplies of milk and meat had been given to expectant and nursing mothers in needy circumstances and to children up to 5 years of age requiring them. The cost of milk thus supplied had been £21,600. The principal feature of the housing situation was the overcrowding in the small houses of the city which continued to much the same great extent as had prevailed in the previous year. The method of meeting the housing shortage by substituting rooms was becoming prevalent in certain districts, and contributed largely to the overcrowding in small houses. Thus, it is pointed

out, reflects most unfavourably on child life by producing a high incidence of diseases such as pneumonia, measles, and whooping cough.

#### MENTAL DEFECTIVES IN FIFE HIPE

A conference was held at Tarrit House, Cupar, on June 10th, to discuss the problem of treating mental defectives in the county of Fife. Dr P. D. Clark, superintendent of the Royal Scottish National Institution, Perth, gave an address in which he said that the mistake in connexion with promoting schemes for helping the mental defective had been that their administration was entrusted to a number of small bodies such as parish councils, education authorities, etc., and this led to uneconomical management to support an institution with economy a unit of 1,000 should be aimed at. The education authorities should combine with various parish councils and the district board of control ought to get together and provide more accommodation. In Fife there were 76 mental defectives not chargeable, 122 chargeable, 32 at home, 20 boarded out, 18 in poorhouses, 46 in institutions, and 18 known to parish councils to be waiting admission making a total of 338. Dr C. G. A. Chislett, medical superintendent, Stoupeville, said that Scotland was far behind in the care of the mental defective although education authorities had made great progress and had established special schools. A resolution was adopted that the conference should memorialize the District Board of Control of Fife and Kinross with a view to having mental defectives provided for institutionally.

#### PROPOSED NEW EDINBURGH HOME FOR BLIND WOMEN

The 134th annual general meeting of the Royal Blind Asylum and School, Edinburgh, was held on June 16th. Sir John R. Findlay, who presided, stated that during the past year £30,055 had been directly paid to blind persons in Edinburgh by way of wages, allowances for maintenance, etc. This was about 66 per cent of the money subscribed to the institution, the remaining 14 per cent was used for administrative expenses. The amount of attention and study given to the training of the blind was he said one of the most remarkable and unobtrusive developments of the last fifty years; there had been a great increase in the number of men put forward for training. Sir Poot Gordon Gilmore, speaking of the adoption of the report, spoke of many graduates of universities who had been pupils of the Blind Asylum and School, and referred to the proposed home for blind women. The Rev. Dr T. Burns, chairman of the district, proposed a resolution affirming the need for a home for blind women to be erected at Alfred Place, Newington, to replace the home at present situated at West Clerkhill. It was proposed to erect a building with sufficient accommodation at a cost of about £16,000.

#### Ireland.

#### CANDIDATES FOR MEDICAL REGISTRATION COUNCIL

The Executive Committee of the Irish Committee of the British Medical Association, Irish Medical Association, and Irish Medical Committee have approved the candidature of Dr M. P. J. Hayes and Dr P. J. Porter for election as the two direct representatives of the medical profession on the Free State Medical Registration Council, under the Medical Practitioners Act, 1927, and recommend the profession to support them.

#### PRECAUTIONS AGAINST THE SPREAD OF SMALLPOX

The Minister of Local Government and Public Health (Irish Free State) has addressed a circular letter to the Joint Urban and Rural Sanitary Authorities drawing their attention to the prevalence of smallpox in England and the necessity of making protective regulations of a temporary character with regard to the importation of infected bedding with a view to guarding against the spread of the disease. Accompanying the Minister's letter

was a copy of the regulations which will operate as from September 1st next. The following is a summary of their purport:

1. Articles transmitted by the postal service or forming part of passengers' luggage and goods in course of transit through Great Britain to an outside destination (if suitably packed) will not be subject to restrictions.

2. Second hand clothing, used bedding, and rugs accompanied by a certificate of the medical officer of health of the place of origin or of the port of arrival in Ireland that they have been efficiently disinfected may be imported in the same manner as at present.

3. Such articles accompanied by a certificate from a medical officer of health in Northern Ireland that they have not been imported from Great Britain may be imported as at present.

4. Such articles not coming within the above mentioned description may be imported only through the ports of Dublin, Cork, Waterford, or Galway.

It will be the duty of the Port Sanitary Authorities of the four ports named to undertake the disinfection of the articles and to return them to the custody of the Customs and Excise Authorities. The Port Sanitary Authorities are directed to proceed at once to ascertain that their disinfection facilities are adequate and effective for dealing with the new service and are asked to confer with the local representatives of the Revenue Commissioners (whose acceptance of the regulations has been duly obtained) with a view to ensuring that the arrangements shall operate without inconvenience or undue delay.

## India.

### HOSPITALS AND DISPENSARIES IN THE NORTH-WEST FRONTIER PROVINCE

The completion of the main buildings of the new city hospital at Peshawar during the present year will permit the creation of the Peshawar Hospital, which was old, insanitary, and unsuitable for the demands made on it, not only by the city, but by the province as a whole. In his annual report for 1925, Lieut.-Colonel C. I. Butler, I.M.S., chief medical officer for the North-West Frontier Province, states that during that year, in spite of the adverse conditions prevailing, more than 60,000 patients were treated and 7,015 operations were performed. Towards the middle of 1925 a site was obtained for a new city hospital, which should not only serve the needs of Peshawar city, but should also become the central medical institution of the province. The foundation stone of this building was laid in March, 1926, by Lady Reading. The port now completed will be adequate for local needs, and additions will be made as funds permit, until it reaches the standard of a large provincial hospital and is equipped on the most modern lines. A new city hospital has also been erected in the Bannu district. During the year under review six private hospitals in the province dealt with over 50,000 patients; five of these hospitals belong to the Church Missionary Society, and the sixth—the Victoria Diamond Jubilee Hospital—is solely maintained by Rai Bahadur Karam Chand. The total number of medical institutions in the province at the end of 1925 was eighty-five, and the aggregate of patients treated during the year was 855,000, an increase of more than 44,000 over the total in 1924. Cholera became epidemic in Bannu but was limited to this district by maintenance of strict medical supervision over travellers along the main roads to neighbouring areas. Tuberculosis is said to be increasing so seriously in the large towns of the province as to indicate the necessity for intensive prophylactic measures.

### ANTHRAX TREATMENT IN THE PUNJAB AND THE UNITED PROVINCES

In the twenty-fifth annual report of the Pathological Institute of India at Kasauli reference is made to the proposed extension of the anthrax campaign in the Punjab and the United Provinces by the establishment of additional centres for its control. Besides the financial difficulty there is the problem of procuring the purity of the serum employed since the most effective preparations deteriorate rapidly, and therefore, the treatment has to

be given at the place where the vaccine is prepared. Lieut.-Colonel J. Cunningham I.M.S., director of the Kasauli Pasteur Institute, states that during 1925 the policy of decentralizing treatment was continued, subsidiary centres being opened at Lahore and Rawalpindi, which, with the centre opened at Allahabad in 1924 were supplied with vaccine from Kasauli. 8,623 cases of anthrax were treated during the year under review with the older and more stable type of vaccine, which consisted of carbonized killed cultures. Improvements have been made in the collection of statistics, with the result that 80 per cent of the patients treated at Kasauli, 94 per cent of those at Lahore, and 100 per cent of those at Rawalpindi and Allahabad were cured. The death rate so obtained was 1.5 per cent during the year, and the rate of failures in treatment was 0.95 per cent. Nearly all the fatal results occurred in patients who had sustained bites on the head or neck, or deep wounds of the body and limbs. Bites on the face were shown to be over six times more dangerous than those on the limbs, and the risk was increased nearly ten times when free injuries were complicated by wounds of the trunk or extremities. Bites on the hands or arms were found to be twice as serious as those on the lower limbs, but body wounds appeared to entail little danger to life. The importance of early treatment is illustrated clearly by the statistics, and the necessity for providing centres for all thickly populated areas receives further endorsement. Colonel Cunningham agrees that rabid bites are twice as dangerous as those of dogs, the number of patients bitten by wolves was too small for definite conclusions to be drawn, but the mortality was evidently high.

### THE PROGRESS OF THERAPEUTICS IN INDIA

In his presidential address to the Section of Medical and Veterinary Research of the fourteenth Indian Science Congress, at Lahore, last January, Major R. N. Chopra, I.M.S., professor of pharmacology in the Calcutta School of Tropical Medicine, commented on the inadequate attention paid in India generally to the teaching of pharmacology, and attributed to this deficiency the prevalence of irrational therapy which was retarding medical progress. Besides eight colleges which trained annually some 600 medical practitioners, there were, he added, a large number of small medical schools continuing many thousand students who eventually commenced practice for the most part without registrable qualifications and without any real comprehension of the science of therapeutics. Moreover, even in the best medical schools, too much of the instruction given was theoretical only, and most of the teachers were handicapped also by being engaged in private practice. In spite of its obvious importance as the basis of successful therapeutics, very little time was allotted to pharmacology in the curriculum and few schools had adequate equipment for the necessary practical demonstrations. Major Chopra therefore advocated the complete remodelling of the teaching of this subject in order that students might learn to be more scientific and less empirical in practice. He added that while some of the clinical and teaching posts in educational institutions might well be held by general practitioners, the appointment of whole time professors and lecturers would materially improve the teaching and would facilitate research. He condemned the provocation to irrational drug therapy afforded by the profuse advertising of proprietary preparations, and thought that legislation might well be introduced in India to restrict the use of new remedies which had not been adequately tested by experimental methods. Standardization by the Government of the therapeutical efficiency of the alkaloids and similar drugs prepared in India was urgently necessary, in the case of imported substances insufficient attention was still being given to the question of their deterioration due to climatic influences. Thus the practice of scientific therapeutics was rendered very difficult. More control of dangerous and narcotic drugs was required. Major Chopra suggested the institution of some central organization similar to the Medical Research Council so that pharmacological and therapeutical researches into the special problems could be started on a large scale. In this connexion he mentioned the need of a

systematic effort to do over-effective treatment for filariasis and guinea worm infection. Other conditions requiring investigation on similar lines were malaria and epidemic dropsy. The training of research workers at such a centre would enable concentrated attacks to be made by co-ordinated groups of workers on the problems concerned in the treatment of various diseases. Major Chopin believed that such a stance given by the Government to research would stimulate private generosity and result in the endowment of similar institutions, the coincident improvement of medical education resulting from such activities would tend to raise the standard of medical practice, with great gain to the country as a whole. Such a central research organization might also concern itself, most advantageously, with veterinary medicine and such allied subjects as zoology and botany.

## Correspondence.

### LAW & MEDICAL TRIAL OF MENTAL DISORDERS

SIR,—Owing to want of time no opportunity was given to me to reply to the discussion in the Mental Diseases Section, yet it would be discourteous not to reply, however briefly, to the observations of Dr. Risien Russell, since to make the case journeyed specially to Edinburgh. They are paradoxical and self-contradictory, and indicate the introduction of unsolved conflicts in Dr. Russell's mind.

Dr. Russell begins by saying that he would be content to enjoy the privileges available in Scotland. The chief of these is that medical men are paramount in a medical question, and that no layman ever sees the patient or encroaches on the domain of the physician to prescribe what course is required for the treatment of an illness. Dr. Russell was fully aware of these facts, nevertheless with this knowledge he next proposes that no patient should ever be placed in a mental hospital for treatment without a full trial before a representative of the law, in which the medical man should give evidence on oath, as in a criminal trial, and be subjected to cross-examination like any other witness. While content to enjoy the privileges available in Scotland, he proposes the very antithesis of the practice in Scotland, and what the Scotsmen would regard as anathema.

Dr. Russell has had some experience of mental trials, he knows how the subject stimulates forensic fury, so that they may go on for days and even weeks. Does he imagine that any busy practitioner will ever allow himself to be involved in such a waste of time or expose himself gratuitously to such offensive observations as he may expect in cross-examination?

Dr. Russell, to carry out his views on their logical conclusion, has as little regard for the welfare of the sick patient as for the time and feelings of his doctor. In a case of urgency, in which the patient requires immediate care and treatment, Dr. Russell would allow no action to be taken by the patient's natural guardians and his family doctor under the certificate of emergency until a lay official visited the patient and granted authority for this. I wonder how many certificates of emergency, if any, Dr. Russell has signed? Has he had any experience?

To keep the legal procedure pure and undefiled, Dr. Russell considers that the legal representative who presides at this mental trial should not be a barrister trained in medicine, that he *must* would leave the matter too "medical," hence the importance of having, as justice, a man with no medical training. Medicine according to Dr. Russell's views, is a source of contamination, and if a barrister is unfortunate enough to have become infected with the virus, he is, if not debarred from this judicial post, at least deemed unsuitable.

We now come to the next paradox. Mental hospitals are naturally better equipped for the treatment of mental disease than most nursing homes or hospitals: their staffs have special knowledge and skill, they are administered under stricter regulations, and they are regularly inspected. Whilst the greatest obstacles are to be placed in the way of

patients obtaining treatment in mental hospital, every facility is to be given for their treatment in places in which the accommodation, the equipment, the staff, and the management may be anything or nothing and there is no inspection of these. Dr. Russell himself has had some experience of mental disease but some physicians may not have had as much as he, and others none at all. All the medical men, however, are to be allowed to treat mental patients, according to him, in any place they wish and without any interference from the law for at least a year, but not so mental physicians in mental hospitals. Many people would be prepared to say that such a rash and unjust proposal could only have come from someone ignorant of the problem and of the history of the care of the insane. It is simply throwing the door open to exploitation of the insane and to every kind of abuse.

Dr. Russell has no faith in the members of the honourable profession of medicine. Yet it is no more than the truth to say that in no country in the world does the average standard of care and treatment in mental hospitals stand higher than in our own. While in our courts of law, the perfect justice of which has never been questioned, there have been in recent times an Adolph Beck and an Edalgi case, in our mental hospitals a Special Committee and a Royal Commission have both failed to find a single instance of wrongful detention, and for seventy years and more no such instance has been found in Scotland. Such a record of careful and honourable service in a very difficult problem is beyond all praise. Fortunately for the profession of medicine and for the sick in mind, there can be few who hold Dr. Russell's views.—I am, etc.,

GEORGE M. ROBERTSON

University of Edinburgh Aug 6th.

### VARIATION IN THE SEVERITY OF EROUPOUS PNEUMONIA

SIR,—In the valuable discussion upon the treatment of eroupous pneumonia in the Section of Medicine at the Edinburgh Meeting there was one point which did not receive the attention to which it is entitled—namely, the variability in different years in the virulence of the infection.

Some years ago I published a series of consecutive cases of eroupous pneumonia occurring in my wards in the Royal Victoria Hospital. The cases numbered 100, and were spread over a period of seven years. The average mortality was 20 per cent, but the interesting point is that in two of the seven years the mortality was 40 per cent, and in other two years there were no deaths.

It is clear that unless this variability is allowed for methods of treatment are liable to a certain amount of failure.—I am, etc.

JAMES ALEX. LINDSAY, M.D., F.R.C.P.

Edinb. Aug 6th.

### FRACTURES OF THE FIRST CERVICAL VERTEBRA

SIR—Mr. Jefferson's admirable paper on fractures of the first cervical vertebra (July 30th p. 155) contains one observation of considerable importance which I should like to support from neurological experience of similar conditions.

In observing that the common cause of the particular fracture he describes is an injury to the head, he records the opinion that the cervical lesion is apt to be overshadowed by the cranial and so to escape recognition. I have not encountered a fracture of the atlas—or if so have not recognized it—but I can recall the details of three cases with fractures at a lower cervical level, which were not suspected until the patients after they had been discharged from the hospital where they had been admitted and treated for cerebral contusion presented themselves with complaints or root pains, limitation of movement, and in one case symptoms of a minor degree of cord compression.

Another condition equally liable to be overshadowed by an associated head injury is a small haematoma in the cervical cord. The absence of any gross physical signs in such a case renders it especially likely to escape

recognition unless the observer is alert and prepared on the patient's complaint of weakness pains or paresthesiae to make a thorough neurological examination.

A cervical haematomyelia is caused not uncommonly by direct violence to the head from above, of the same type as that which Mr. Jefferson describes in fracture of the atlas. Even a small haematomyelia may, on account of destruction of the anterior horn cells, cause serious permanent disability. I recall the case of a dock labourer who had been in hospital for a severe head injury from which he recovered, but afterwards complained of weakness in the right shoulder, which prevented him from raising heavy weights above his head. This had persisted for a year and he had put in a claim for compensation which was contested on the statement by a well known authority in medico-legal cases of this kind that the man was a malingerer. Neurological examination revealed slight wasting of right deltoid and spinal muscles and extensive loss of pain and temperature sense on the opposite side of the body.

The medico-legal importance of these cases is obvious—I am, etc.,  
London W 1, Aug. 1st C. P. SIMONDS

### THE METABOLISM OF TUMOURS

SIR,—I have read with much pleasure the generous and well-merited appreciation of the work of Otto Warburg contained in a leading article of your issue of August 6th (p. 221).

The last sentence in the article, "*The repetition and extension of his work in this country should not be longer delayed*" (the italics are mine), expresses a hope which Professor Lewis and some of the physical chemists working with him on behalf of the Liverpool Medical Research Organization have been fulfilling for the last eighteen months. I have made frequent references to this work, on more than one occasion, indeed, in the *BRITISH MEDICAL JOURNAL*. Directly Warburg's work came to our notice we realized the importance of it, and two of our chemists went immediately to Berlin to obtain first-hand information regarding the somewhat difficult technique. They were cordially received by Professor Warburg, and through his good offices obtained a duplicate of the actual apparatus used in his laboratory.

As I have already stated on many occasions, we have fully confirmed the main issue, namely, that malignant tissues exhibit a high degree of glycolytic power in the presence of oxygen, and can thereby be distinguished from benign neoplasms and from normal and somatic embryonic tissues.

With regard to extensions of this work on which we have been engaged, I shall say no more here than has already been published. Contrary to the views expressed by Warburg and in accordance with the results of Murphy and Hawkins of the Rockefeller Institute, we have found that the chorionic epithelium acts like a malignant tissue—an essential point in the confirmation of our views as to the nature of malignant neoplasia.

All this part of our work will shortly be published, and then we shall, I think, be able to explain why Warburg's findings in regard to the placenta differ from our own. We hope, too, shortly to publish other observations of considerable importance—I am, etc.,

Clifton Bristol Aug. 8th

W. BLAIR BRY

### RESULTS OF TREATMENT OF UTERINE CANCER

SIR,—With reference to the report recently issued by the Ministry of Health and your review thereof, in Section A, Part II, is contained a number of tables bearing on the results of different forms of treatment according to the stage of the disease, and on pages 101 and 102 there is a table (Appendix 12) concerned with abdominal hysterectomies, in which Bonney is credited with having performed and published the results of 114 operations, and Berkeley and Bonney the results of 65 operations on cases in which the disease was "early" and "still local." In a footnote it is admitted that the cases of ours were grouped on

the fact that the regional glands removed at the operations were not malignant, and the reason given for their inclusion in Table A is that the operative results of these series were almost identical with groups of cases classified and published by other surgeons as "early and still local" on the interpretation of pre-operative findings.

We strongly dissent to the inclusion of our cases in this table. There is no constant relation between the degree of advancement of the growth in the cervix and adjacent structures and the involvement or not of the regional glands. On the average of course, the extent of the growth in the cervix and adjacent tissues is less in a group of cases in which the regional glands are found not involved at the operation than in a group in which they are involved, but there are a great many exceptions, and among these cases of ours were many in which the growth was very extensive, and in which resection of a uterus or part of the bladder, or even a part of the rectum, was necessary in order to remove it. Indeed, we would point out that the decision to carry through an operation in which the growth in the cervix and adjacent parts is very extensive is frequently determined by the fact that, after opening the abdomen, the regional glands on palpation are judged not to be encroaching. For instance, the formidable step of resecting and grafting a uterus, or deliberately resecting a part of the bladder, is more likely to be undertaken if it is believed that the regional glands are not involved, and, as a fact, in much the larger proportion of cases in which we have gone to these lengths, the glands removed at the operation have proved not to be encroaching. The classification of cases of carcinoma of the cervix into "early," "medium," and "borderland" on the interpretation of pre-operative findings, even when carried out by surgeons experienced in Wertheim's operation, is inaccurate, and has no value at all when attempted by persons having no such experience.

The classification we have adopted is accurate, since it is founded on the microscopical examination of the glands removed at the operation, and its value is that it clearly separates off those cases in which a cure by radium applied from the vagina would appear to be impossible—namely, those in which the regional glands are already encroaching by the time the patient comes under treatment.

We wish also to point out what appears to us to be another error in the report. On page 38, Appendix 5, Table A, Waid and Irons in 1925 are credited with 71 patients treated by radium, of whom 40 survived five or more years. From a reprint of what is presumably the same paper kindly sent to us by Dr. Guy Waid it appears that the figures should be 72 treated cases of whom 17 were living at the end of five years.

As regards the main purpose of the report—namely, to ascertain from statistics the comparative values of operation and radium in cases in which either can be employed, we believe that a decision should be postponed until fuller and more numerous results of treatment by radium are forthcoming from British sources. At present, from a personal experience of many years in the treatment by radium, and our knowledge of the work and experience of others in the same field in this country, we are emphatically of the opinion that operable cases should be operated upon—We are, etc.,

CONYNS BRIDFAY  
VICTOR BONNEY

London W 1, Aug. 8th

### THE PROPOSED NEW HOSPITAL POLICY

SIR,—In expressing appreciation of Mr. H. V. Groves's courageous article in the *BRITISH MEDICAL JOURNAL* of July 23rd (p. 131) on our present hospital system, I should like to mention one or two points supporting his argument. There must be many men who, like myself, have had much experience in voluntary hospitals, and who now are working in other hospitals and various kinds of municipal and State medical services, and who agree with every word Mr. H. V. Groves has written. His propositions are somewhat similar to the system at present used in Germany and Austria, where it appears to work better than ours, especially in the matters of research, education of students, and correlation of the work done.

Thus the number on the staffs of Poor Law hospitals are extremely small in comparison with the number on the staff of voluntary hospitals. This would not matter if, as formerly, the class of patient were of the chronic type, but this is no longer the case—about two-thirds of the cases admitted to this hospital are now exactly similar to the cases admitted to voluntary hospitals, and the other third consists of these cases, never admitted to a voluntary hospital but which form the bulk of the cases with which the general practitioner has to deal from day to day, such as abortion, acute bronchitis, pneumonia and cerebral hemorrhage. And there is a constant scrambling for beds on the part of the staffs of voluntary hospitals especially the junior staff, there is a great waste of material for observation and research going to waste in the Poor Law hospital for want of adequate staff.

Secondly in the matter of education of students the present staffs of voluntary hospitals are becoming too much specialized. One surgeon becomes known as a gastro-intestinal surgeon, another as a kidney surgeon etc., with the result that their wards are filled with such cases, to the exclusion of others. This is bound to be so since the patients admitted to these wards are sent to these surgeons by general practitioners—either to the out-patient department or to their consulting rooms. It thus happens that the doctor, during his term of office is apt to see a great number of cases of one kind and a very few of any other. On the medical side the position I believe is even worse. The beds available only admit of the entrance of interesting cases also in one ward neurological cases, in another chest cases, and so on. The student is in this way being trained as a specialist before he has even had the opportunity of seeing the general run of cases with which he will have to cope when he enters practice. Then he finds that he can forget most of the specialized training he has received, and he has to start out learning his job for himself.

It seems to me that only by some system which will correlate and share the work now done by the voluntary and the Poor Law hospitals can the treatment of the patient, advancement in research and the efficient teaching of the student be attained—I am, etc.

J S M CORNFELT F R C S Ed

Birmingham July 31

SIR—In answering your correspondent's comments on my recent address, may I begin by thanking Dr Gordon, Mr Gibson, and Mr Fleming for their kind remarks, and at the same time say how greatly I have been encouraged by the many private letters of commendation which I have received.

Dr Ackman asks whether I have overlooked the fact that the two great hospitals of this city have refused to unite in forming a common scheme for hospital reform. Certainly I have not. During the last five years, besides the Voluntary Hospital Commission there have been three distinct attempts to bring about hospital amalgamation in this city. The first was made from the common sense business man's point of view by the late Mr W. H. Wells, the second by the united staffs of the two large hospitals and the third and most recent by the University. The history of each has been the same, the policy of amalgamation has been forcibly put from the economic, the clinical, and the educational aspects, and the arguments in its favour have never been answered. But the managing bodies of both institutions have always refused to take any practical steps to bring about the desired change.

Dr Fleming writes of 'want of vision the conservatism, the individualism the parcelled out of some of the governing bodies concerned', and it is the cause of the 'vision' that I believe it to be hopeless to expect a reform now within, and why I earn the sobriquet of *drusus machina* which will break down the present system and the first step toward building up something better.

Dr Morton objects to my proposals as being impracticable. The exigencies of space did not permit the publication of the full part of my address in which I spoke of visits to the hospitals of Canada, Denmark and Switzer-

land, in all of which countries the hospital plan which I am advocating is in operation. I also referred to the hospital policy of Madrid in which there are now three large general hospitals of out-of-date type and it is not possible to dilute. They cannot be enlarged or modernized because of want of space, moreover any attempt at enlarging these hospitals full equipment of apparatus and personnel would involve tripling the men and things. The Government have therefore decided to build a university city on high ground on the outskirts of the present capital and there, unhampered by considerations of price, to build the ideal university hospital in which every department will be as perfect as modern science can make it.

If any of your readers agree with Mr Morton that the voluntary hospitals are very well equipped and very efficient even having regard to the requirements of the present day, then I could beg such people to spend a business holiday at Toronto, Copenhagen or one of the Swiss cities and to tell us when they come back whether they are still satisfied.

Mr Morton, in opposing the ideal of a country hospital site for the main general hospital is rather hard pressed for reasons. He thinks the cleanliness of the country negligible for cases of pneumonia or tubercular disease, and I will leave that as a matter of opinion. His first of the advantages of the city site for a hospital is being accessible to the visiting staff and the students, but actually none of the visiting staff live in the city, neither do the students. All now have to go two or three miles to visit the hospitals and they might just as well go two or three miles in the opposite direction. But apart from cleanliness and quiet there is the very urgent need for room for extension. The city hospitals cannot be built in the modern pavilion pattern because there is no room. Again the matter is urgent on account of the nursing staff who must spend three years or more at the hospital, and some of whom contract pulmonary disease which compels them to give up their work. Is it wise or right to spend large sums of money in housing nurses in the noisy slums of a dust polluted city?

The immediate need for reform is not the necessity of bringing the country hospital but the desirability of bringing together the present independent voluntary hospitals into a unified scheme for the good of the community. This could be done without any capital outlay but if the Government would allocate three million pounds out of the profits of the National State Insurance to the unrecited cities then I think it that any impartial hospital committee would spend the money on a single new hospital in the country in which to pack up the many existing rival institutions.

Space will not permit me to follow Mr Morton's remarks about specialization. He admits that such increased specialization could be to the advantage of the patient, but not for the economic position of the doctors, and therefore specialization must not be encouraged. He raises a difficulty in the matter of the student's education, if all special branches of medicine and surgery are adequately equipped and properly staffed. Such an argument would not be admissible in connexion with any other branch of science. The chemist, physicist or biologist to be told that his science must not be further elaborated because the undergraduate will not be able to comply with the course of study. The undergraduate students of medicine must be taught the essential principles of their science and not by teachers and tutors who combine to give an undergraduate curriculum. The more recalcitrant specialties must still be pursued in the case of the patient for the sake of research and for purposes of post-graduate teaching—I am, etc.

Chilton W. 24

FREDERICK W. HENCH

#### REMUNERATION OF HOUSE APPOINTMENTS

SIR—There must be a number of newly qualified practitioners present and future house officers who would welcome the ruling as it appears in the *British Medical Journal* in 1921 in which the conditions of appointment of house and residents, and the present scale of remuneration

the number of applications for these posts to fall suggests that the time is opportune for discussion and co-ordinated action.

No one who studies the advertisement columns of the *Journal* can fail to be impressed by the inconsistencies which exist in the remuneration of house officers, the salaries offered varying from nothing to £200 a year. After some five years' training a medical man should be able to command an adequate remuneration, and the average salary of £100 a year can hardly be said to fall within this category. The experience gained as a resident by a recently qualified practitioner is valuable in putting the finishing touches on his education, but it is doubtful whether this is not amply repaid by the strenuous and often onerous duties of the house officer. In the smaller hospitals, where only one or two residents are employed, there is often, in addition to the usual medical duties, a large amount of clerical and administrative work, especially where no whole-time secretary is available. The house officer has gained a very real and indispensable position in the life of the community, and the fact that the holder of a resident appointment is gaining further experience while discharging his duties should not be an excuse for offering a remuneration which is considerably less than that obtained in other professions by actual apprentices.

The salaries of house officers should be substantially revised, and, for the purposes of grading, appointments could be conveniently classed as senior and junior according as to whether previous resident posts have been held. In cases where only one resident is required, the salary should be that of a senior appointment. Only in the cases of bona fide teaching hospitals, recognized by the universities, should a reduced figure be allowed, and the practice of appointing honorary house officers is much to be deprecated. There must be many promising men who have to forgo the kudos of holding a post in their teaching hospital on account of their inability to afford the inevitable preliminary wait for an appointment and the subsequent period without remuneration.

In all cases where short lists are compiled, and candidates interviewed from a distance, reasonable travelling expenses should be granted. If a candidate is worth interviewing he is worth his expenses, and such an allowance is practically a guarantee that due care will be taken to prevent needless and expensive journeys, for the desire to economize now becomes mutual.

Lastly, it is desirable to call attention to a practice which some metropolitan hospitals have adopted of asking candidates to call on members of the staff when applying for an appointment. It is difficult to understand the need for this, which involves much inconvenience and waste of time, and which excludes all applicants who happen to be outside the London area. In the case of permanent staff appointments no objection can be raised, but, in view of the fact that house posts are at the best only temporary, the requirement seems neither reasonable nor necessary.

The British Medical Association has done much in the past to raise the status and terms of service of the established medical profession, and its opinion and guidance in the above matters would no doubt be appreciated by that small army of house officers whose ranks are so constantly changing that it has no opportunity for an organized action.

As a present resident I beg to take refuge in a simple title—I am, etc.,

“HOUSE-SURGEON”

#### DEATH CERTIFICATION

Sir,—On July 1st the Registrar-General distributed new forms for death certification to the medical profession. These are so designed as to ensure more accurate information, by eliminating the necessity of furnishing the relatives with the technical causes of death. A woman, aged 68 died in a nursing home in Putney. I filled up a certificate (a) coma vesicles (b) cirrhosis of liver, known for years. The local registrar refused it and referred the matter to the police. The coroner's officer called. In constable visited the home, pestered the

matron with questions, and refused to refer to me on her suggestion. Last night the coroner's officer rang me up to say that the post-mortem examination had shown my diagnosis to be correct. Neither the matron nor I have been summoned to the inquest. Wandsworth is the largest borough in London, and the inevitable result of this unmanly interference with the doctor's certificate will be that the registrar will not obtain the correct information that it is so important for him to receive. I have done my bare duty, and the relatives are gravely annoyed with me. Is it not possible to take some action that will prevent such pettifogging interference with the registrar's returns on the futile grounds that death was not due to natural causes. It is surely unnecessary for me to emphasize the lack of respect shown to the profession in the high-handed neglect of the doctor in charge of the case—I am, etc.,

East Sheen, July 31st

#### Obituary

WILLIAM JONES GREER, F.R.C.S.I.,

Surgeon, Royal Gwent Hospital, Newport, Mon

THE news of Mr Greer's death, which took place at Llanwrtyd Wells on August 3rd, was received with profound regret, not only amongst the medical profession of South Wales and Monmouthshire, where he was so well known, but also in a much wider circle amongst surgeons in England, where his work was highly appreciated.

Mr Greer, who was an Ulsterman, was born in the city of Armagh, and received his early education at the Royal School in that town, he pursued his medical studies in Queen's College, Belfast, and the Schools of Surgery, Dublin, and obtained the diplomas of L.R.C.P.I. and L.R.C.S.I. in 1891, after a further period of study he received the F.R.C.S.I. and D.P.H. in 1895. He settled in Newport, Monmouthshire, in 1896 as a general practitioner, and after a few years' hard work his success was undoubted. During these years he performed many major surgical operations on patients in their own homes, and he soon gained a local reputation as a surgeon. He then relieved a most difficult feat, he relinquished general medical practice and started again as a consultant surgeon. Although he was not at that time on the staff of any hospital his success was almost immediate, and he became known to his professional colleagues in Monmouthshire as a brilliant operator. Hospital distinctions came later, he was appointed honorary surgeon to the Royal Gwent Hospital, Newport, and consulting surgeon to the Blaenau and Pontypool Hospitals. He was a major R.A.M.C. (T.F.), and during the war was on the surgical staff of the 3rd Western General Hospital at both Cardiff and Newport. His work during the war years was very strenuous, and undermined his health, which was never very robust. He contributed many articles to the medical journals from time to time, and was the author of a book on *Industrial Diseases and Accidents*, which was, and continues to be, very popular, not only with the medical profession, but with barristers having charge of cases under the Workmen's Compensation Acts in the County Courts.

His work for the British Medical Association will not soon be forgotten in South Wales. He was the first secretary of the Monmouthshire Division, and during his years of office the famous contest with the Ibbw Vale Workmen's Fund took place. The heaviest portion of the work fell on his shoulders, and he guided his medical brethren with rare skill and wise judgment. When he relinquished the position of secretary he received a valuable gift, subscribed for by all the members of the Division. Amongst other offices which he held in the Association were representative for many years, deputy-chairman of the

in 1919, member of the Central Council, chairman of the Monmouthshire Division, president of the South Wales and Monmouthshire Branch, chairman of the Committee on Fracture, and a member of the Medico-Political and Parliamentary Elections Committees and of the Contract Practice Subcommittee. He

The address of the Irish Office of the British Medical Association is 16 South Frederick Street Dublin (telegrams, *Macillus Dublin* telephone 4737 Dublin) and of the Scottish Office, 6 Drumshough Gardens Edinburgh (telegrams, *Associate, Edinburgh*, telephone 4361 Central).

### QUERIES AND ANSWERS

#### A "BORDER LINE" HOME WANTED

"OXY" wishes to hear of a "border line" home for patients of strictly limited means. The patient is an ex-service chaplain, who has for the last year been having epileptiform attacks, during which he is mentally confused and requires the attention of a male nurse. At other times he is quite normal.

#### INCOME TAX

##### Replacement of Car

"R. W. M." bought a car in 1922 for £400, in January, 1926 he replaced it by another, which cost £289 less £80 received for the old car—that is, £209. If he had bought a car similar to the one displaced the cost would have been £235—£80=£155. He claims to deduct £320 as the 'depreciation figure', the local inspector has allowed £155 only.

"\* \* The Income Tax Acts do not make any allowance for 'depreciation,' except the percentage allowance, which has applied to the past year or two, so far as professional men are concerned. Any other allowance is based on the cost of replacing a discarded asset by a similar one, and on that basis the inspector's allowance seems to be technically correct, though obviously inadequate to cover the full 'depreciation'."

#### Ascertainment of Consultant's Earnings

"I. T. W." has submitted a statement to the effect that he commenced practice, mainly consulting, in November, 1926 and for the first five months—to April 1927—has lodged a statement showing a professional loss of £253—that is, gross earnings £34, less expenses £297. The local inspector of taxes declines to accept the result as correct for income tax purposes.

"\* \* The statement seems open to attack at three points (1) Is £34 the gross amount of earnings on the basis of what is due and will probably be paid for the work of the first five months, or is the £34 the amount of the cash received in that period? The latter basis is inapplicable to such a case as this. (2) Is £50 a fair charge for quasi domestic service, having regard to total cost and the ratio of time expended by the maid in connexion with the professional side of the establishment? (3) Cost of running the car (including depreciation and chauffeur's wages) £202, this seems excessive for work represented by the fees stated. What our correspondent should do is to ascertain the total amount expended (preferably not by estimate) and divide it on the ratio of the mileage for professional and private use respectively. I think we cannot advise "I. T. W." to press for the acceptance of the figures as they stand."

### LETTERS, NOTES, ETC.

#### TREATMENT OF VARICOSE VEINS BY INJECTION

Dr. A. H. DOWLING (Worthing) writes: Major General T. M. Carter has assumed that there is no danger of embolism resulting from the treatment of varicose veins by injection. I have given over 2,000 injections without mishap and similar results can be obtained on the Continent. Thrombosis of the veins can occur but the clot is firmly rooted in the wall of the vein.

### DIFFERENTIAL DIAGNOSIS OF SMALL POX

In a paper published in the *Indian Medical Gazette* of April 4th Dr. J. W. Lamb, chief sanitary officer to the Assam Valley Board of Health in Bengal, states that greater accuracy can be obtained in the differential diagnosis of small pox from chicken pox by ascertaining the interval between the onset of fever and the outbreak of the eruption. In an investigation at Assam it was found that this interval never exceeded twenty-four hours in chicken pox and always exceeded forty-eight hours in small pox. In cases diagnosed as chicken pox during one or two years preceding the investigation, revaccination was successful in practically the same proportion of persons as in the general population. But in 103 patients who had been diagnosed as suffering from small pox by the same criterion of interval in the same period, not a single revaccination was successful. Dr. Lamb urges that all public health authorities in India should adopt the method of diagnosing small pox by the time interval between the 'date of onset of fever' and the 'date of outbreak of eruption'. At the same time he admits that in certain cases of a vesicular eruption unaccompanied by fever, to which the term 'alastrum' has been applied, the method is impossible.

### ETIOLOGY OF RHEUMATIC INFECTION, ETC.

"C. M. H." (Hong Kong) writes: I would like to suggest that a close study of the tropical and subtropical distribution of some diseases prevalent in temperate climates would throw light on their cause and treatment. Years ago I was asked why rickets was never, or almost never, seen in Hong Kong, a big city with many slums, and why children could thrive for long periods on an exclusive diet of condensed milk. This was before the days of vitamins and ultra violet ray treatment. The absence of rheumatic fever and chorea from Hong Kong suggests that these diseases may have an etiology and cure on somewhat the same lines as rickets has. Amongst thousands of post mortem examinations in Hong Kong I have never seen signs of any kind of disease, therefore perhaps, there may be a lamp or diet treatment which would prevent or cure this disease in England. The seasonal prevalence and mildness of diphtheria and scarlet fever in hot countries makes it probable that if the scarlet fever and diphtheria wards of English hospitals were to be maintained at a high temperature, then the diseases would run a shorter course and 'return cases' be scarce. A temperature not allowed to fall below 86° F. would probably be sufficient. I have noticed many times when a calf was vaccinated during the late stage of the incubation period of rinderpest, that, after the temperature of the animal rises, the commencing vaccination rapidly aborts. This suggests that there must be some way of aborting a small pox eruption, and that temperature will be a factor in it.

### A GUILD OF HEALING

The Guild of St. Raphael, founded in 1915, is endeavouring to restore the Ministry of Healing "as part of the normal function of the Church." At the annual meeting Dr. H. M. Raven of Broadstuns delivered an address, which has now been printed in the quarterly journal of the Guild. It is satisfactory to learn that members of the Guild do not approach a case of sickness without the consent and, if possible, the goodwill of the doctor in charge. Dr. Raven as a good Anglo-Catholic, lays stress on the benefits to be obtained from Holy Union and from the laying on of hands, but he deplores the enthusiasm which reports as a cure of lockjaw the case of a young and highly nervous woman, who went to bed with pain and stiffness in her jaw and was cured by sacramental healing and the extraction of the bad tooth. He has been impressed by the healthy outlook advocated by Christian Science speakers, notwithstanding their curious refusal to face facts, and he thinks that in slow degenerative processes, which do not cause much distress patients would be much more healthy, spiritually and mentally, if they took a courageous view of life and made less fuss. Dr. Raven's address was a cheerful and earnest attempt to inspire the Christian with fortitude and to balance his faith with reason. Whether he is right in saying that the 'gift of healing' is in the hands of certain people who have the healing touch is debatable, but the personality—whatever that may be—which aids the physician in curing patients must assuredly be one of Dr. Raven's assets.

### THE BEGGING LETTER AGAIN

A MEDICAL man in London has sent us a letter addressed to him from Cardiff appealing for a loan of £3 to help the writer's family. The father is described as a former medical student ('you will probably remember him') who failed to qualify and is now seriously ill with consumption. Repayment is promised when 'father's allowance' is received from Australia. Our correspondent wrote to the Cardiff police and learnt that the family are a well known firm of begging letter writers.

### VACANCIES

NOTIFICATIONS of offices vacant in universities, medical colleges, and of vacant residencies and other appointments, at hospitals will be found at pages 38, 39, 40, 41, 44 and 45 of our advertisement columns and advertisements as to partnerships, assistantships, and locum tenencies at pages 42 and 43.

A short summary of vacant posts notified in the advertisement columns appears in the Supplement at page 204.

## A Review

or

## THE STRUCTURE AND FUNCTION OF THE SPLEEN

JOHN FAIR M.D. D.S. F.R.S.

Professor of Physiology and Director of Experimental Medicine  
Mullum University, Montreal

I wish to say what a pleasant thing it is for me to be back in a familiar lecture-room under the presidency of my distinguished chief and teacher of physiology. When in 1899 as a young student I attended the first course of lectures that he gave as professor in Edinburgh—which I still look back upon with delight—he told me, along with other wonderful things about the known attributes of and about the perplexities that surrounded the function of the spleen. As happened so often in his case the information he gave was from first hand knowledge, for he was fresh from an important investigation on the subject which had taken a winter of work by his pupil Benjamin Moore and himself. That work was fundamental for our knowledge of the muscular and nervous control of the spleen. I wish I could go on to say that there and then I was filled with an eager desire to probe further into the mystery that shrouded splenic function. I can only speak for my classmates, but certainly not for myself, further along the thought. At the same time it was of this mystery that he had on his introduction to the subject in 1901—when he had equal range of the finer structure as displayed by the microscope and over the gross behaviour of the organ as studied under the conditions of its normal laboratory vivisection.

My particular interest in the spleen began accidentally when Miss Menzies (now Mrs. McCartney) and I were engaged in any thing particle of Indian and into the circulation of mammals so as to compare with one of the results previously obtained by similar injection into Crustacea. We found that the particles, even when injected in enormous quantities, were speedily swept out of the circulation and deposited in the spleen, the liver, and in the bone marrow. While the former period slipped past the cells of the vascular endothelium without any tendency to adhere to them, the latter, the liver, spleen, and bone marrow, by contrast and in addition by special cells that here line the blood channels. In other words, in each of these three organs of the mammal there are named areas devoid of the normal endothelial lining and many of the cells situated along the blood vessels are phagocytic. We thought for the moment that we had lighted upon a new fact of obvious importance in connection with blood spread of infections—namely typhoid, kala-azar, small pox, tularemia. Our interest in discussing these diseases had certainly told us little of the extraordinary phagocytic properties of the cells in spleen, liver, and marrow. As so often happens with discoveries so simple and so easily made, other people had been in the field long before us, only their work had been forgotten. We were also unaware that Aschoff had just before us, seized the great significance of the same facts.

This was in the early days of the war. The next thing was that I found myself out in Macedonia treating malaria patients in the return country from which we obtained our spleen, and in 1902, 2500 years ago the organ commanded almost as much attention in connection with sacrificial ceremonies on animals and with disease in man as the brain or the heart does in modern times. To the early Greek physicians—and Galen later reflects the same outlook—the curious variations in volume of the malaria infected spleen possessed an interest that more fortunately situated people find difficult to understand. So prevalent has malaria long been in Greece, but there is reason to believe that this disease, even more than political

It was an amazing experience to come back from Greece and from Macedonia, I should say, and to read the *functio organo* of the head literature Hippocrates, where the history of malaria stands printed on page after page of the most original, the most detailed and objective writing in the whole of medicine. Had we not had unusual medical experience in Macedonia for which our clinical training our pathology had failed to prepare us—cases of black urine, cases of delirium, of coma, bodily disorder, protein in variety and in quantity—regards both rational and treatment? And in our ignorance we had imagined that these manifestations of disease were being seen and recorded by us for the first time in history. Some of you may in your childhood's days have landed on some lone deserted island. As flocks of wild birds rise on the approach of your boat you imagine that you are actually a Robinson Crusoe, sitting fast for the first time on utterly unknown shores. When you get older you discover that your Crusoe island has a proprietor. It has been carefully mapped, measured, and charted, and even had its human population in earlier days to whom every beach, every curve of the coastline, every putting rock was perfectly familiar. So it was on returning from Macedonia to read the story of malaria in Hippocrates.

In the case of this disease Hippocrates finds that the spleen is suddenly enlarged and within a day or two becomes again reduced in size. One of his remarks is: "The spleen is enlarged in the case of malaria, and it is reduced in size when the fever subsides." We examined the children of the army and the soldiers of the army, and we found the level of the spleen. In other words, the enlarged spleen represented the normal condition of the Greek child, whence in point of Hippocrates was not unusual. Could any statement better illustrate the universal prevalence of malaria in his day? Galen informs us that both Hippocrates and Plato considered the spleen as an organ for purifying the blood, a opinion as prophetic as consistent with modern findings as are the ideas of Democritus. If we can make one rational embracing statement about the spleen as it occurs throughout the animal kingdom, it is that it purifies or catenates the blood.

However, this is not a historical lecture. I have to open a discussion in the vein of the Physiology Section of the British Medical Association and under the exacting eye of Sir Howard Crosby, Schafer himself. There are other speakers to be met. Professor Barcroft, who is working on splenic function, has been so fruitful and so illuminating.

## FUNDAMENTAL FEATURES

The spleen is essentially a vertebrate organ, and is steadily present in the mammalian group as an indication of its importance. Comparative anatomy shows that it has certain comparative value in the class we may count fundamental or essential in some animals—for example, mammals—we find it, and it is notably atrophied in the avian and splenic in the chelonian. In regard to secondary acquisitions it is in our animal kingdom to the fundamental features which are suited to particular advantage in the life of the creature.

## The Spleen of the State

This is a tough and it is movable organ, externally quite like the placenta of mammals. It has, however, no lymphoid tissue, no trabeculae, and no special splenic musculature, the only muscle being that which invests the arteries. The firmness of the organ is due chiefly to the strong-walled vessels which invest it. The principle of a tough stringy foundation on which in turn is embedded in a more deformable and divisible cellular tissue of the reticular which serves to envelop all the cellular elements of the parenchyma, are stout reticula, and more conspicuous in the reticulated in the mammalian spleen, yet their strength a dissection shows falls far short of that of a ramifying artery and veins. In other words, so far as mechanical resistance is concerned, the principle of construction in the state spleen is life

sharp y Schafer M.D., F.R.S. President of the Section was in the chair.

The annual general meeting was given in regard to the state of the work done in connection with Dr. E. S. M.

that employed in ferro-concrete, where strings or rods of more resistant material greatly augment the strength of the composition. A fibrous capsule surrounds the whole.

### Development

As Laguesse has shown, the spleen of elasmobranchs as well as of other fishes takes origin as a kind of reticulated venous sinus alongside the subintestinal (later the portal) vein, with which it stands in open communication. At an early stage no regular or rapid blood current sets through it, though delicate ramifying sinuses begin to form defined channels for blood eddies. Arteries eventually penetrate from the exterior into this spongy, sinus-provided tissue. When they have worked their way well into the interior their ends become open, and then for the first time arterial blood pours into the reticulum. As might be expected, the strong-walled veins proper of the organ have been taking form and semblance during the time of involution of the arteries, and now for the first time the natural through-and-through current is established. There are thus two distinct stages in the development of this unique organ, and even after the second stage the circulatory arrangements remain unusual. In the first stage the spleen is a spongy, blood-sodden, yet sinus-provided excrescence on the side of a vein. In the second stage arteries, carrying their muscle coat and their fibrous adventitia with them, shoot in from the exterior. Coincidentally, well formed veins, with fibrous tissue wall, reach inwards as a counterpart to these arteries. Though they tend towards each other their terminations never meet by direct anastomosis. Everywhere between the ends of the tubular arteries and the stout-walled veins lies a mesh, a mass of reticulum with its tunnels, the venous sinuses.

In this description I have closely followed Laguesse. At one point only have I ventured to modify his account. He would have it that the walls of the intrasplenic veins are everywhere formed of compacted reticulum. In point of fact, over a considerable part of their intrasplenic course the walls of the larger veins are composed mainly of tendon-like bundles of wavy, non-branching, white, collagenous fibrils, which may be assumed to have grown in from the adventitia of the parent vein or veins. The spleen of the skate, therefore, consists of arteries which have invaded its texture, of veins, which we may also look upon as having grown in from the exterior, and between these two—what? The original reticulated and sinus-provided spongy which originated in close relation to the subintestinal veins.

### Arteries and Ellipsoids

The arteries eventually terminate in penicillar vessels. Each penicillus gives off near its extremity a small cluster of terminal vessels. Each of these in turn ends in one or more ellipsoids. The ellipsoidal mode of termination of the arteries is a fundamental feature of splenic architecture, and in fishes, just as in mammals, the sessile phagocytic cells of the ellipsoids capture foreign particles introduced into the blood stream and probably also ingest effete corpuscular elements of the blood, this being our modern conception of the "blood-cleansing" process of Hippocrates. It is noteworthy that in the spleen of the skate each terminal vessel comes to a blind end within the ellipsoid. In the mammalian spleen the terminal vessel frequently passes through an ellipsoid and ends beyond it. Whether this peculiarity of the arterial endings in the mammalian spleen is correlated with the presence of the special splenic musculature I am unable to say. The spleen of the skate, which is devoid of muscle, exercises no detectable pumping action, and it is a debatable question whether it acts as a temporary store of erythrocytes as Bancroft has shown the mammalian spleen to do. In texture the ellipsoids resemble those of the mammalian spleen, being composed of very finely meshed reticulum, which is continuous with the general reticulum of the parenchyma.

### Veins and Venous Sinuses

The veins of the skate spleen originate as venous sinuses, this mode of origin being again a fundamental splenic feature. The sinuses have none of the elaborate architecture described by Møller in the case of the mammalian

spleen. They are mere endothelium-lined tunnels in the general reticulum. Although to the eye the lining sheet of endothelium appears continuous, the blood and blood corpuscles can evidently pass freely between the endothelial cells, for nowhere is the uniform continuity of any sinus wall seen to be broken. As in the mammalian spleen, the walled veins do not reach quite so far into the organ as do the arteries, the place of the penicilli being taken by venous sinuses. The disposition of the veins, however, is different from that in the mammalian spleen, in which these vessels are crisscrossed by trabeculae. In the spleen of the skate, which is devoid of trabeculae, venous and arterial branches tend to run side by side, being bound together in a common investment of thickened reticulum. Within this common reticular sheath the larger venous branches have a very stout wall composed of bundles of non-branching collagenous fibrils. In possessing a real fibrous tissue wall both the arteries and the veins of the spleen may be regarded as foreign intrusions lying in the midst of the general reticulum. The venous are invariably of wider calibre than the corresponding arterial branches.

### Fundamental Vascular Features

Let us now review the vascular arrangements, confining our attention solely to the fundamental features. Inasmuch as the arteries and veins have a wall containing real fibrous tissue they constitute intrusions into the splenic reticulum. The arteries are a little longer than the veins, at the level at which the arteries ramify into penicilli the veins give place to venous sinuses. The penicilli break into terminal vessels, each associated with one or more ellipsoids, which are composed of finely meshed reticulum. The ellipsoids contain sessile phagocytic cells, which, after ingestion of foreign particles, migrate into the parenchyma. Within an ellipsoid the endothelial lining of the arteries may come to an end. Between the ellipsoids and the venous vessels intervenes the general reticulum of the spleen. The blood passing through this reticulum enters venous sinuses before reaching the veins proper. Notwithstanding the apparent continuity of the lining endothelium of the venous sinuses, their walls are everywhere porous. The venous are of larger calibre than the corresponding arterial branches.

### The Reticulum

The reticulum of the skate spleen is beautifully displayed by the Bielchowsky staining procedure. Fortunately, too, the Bielchowsky method in this case usually makes a distinction in depth of colouring between the two reticular and the non-branching collagenous fibres present in the wall of the veins and arteries and in the external capsule. Thus the limits of the reticulum can be defined, and we shall devote our attention to the problem of assigning its exact boundaries.

Besides the Bielchowsky method of displaying the reticulum there is another equally instructive method, which serves, too, as a valuable check upon the staining procedure. This is to inject backwards through the main splenic vein a suspension of Indian ink particles, followed by a similar injection of formalin. The latter material, clearing the ink out of the veins and venous sinuses, drives the last of it into the reticulum, which the reagent also fixes—and here I might say that, whatever its disabilities for fixing cells, in its application both to reticular and to white connective tissue fibres, formalin for special reasons stands supreme as a fixing agent. The particles of ink find their way to every available part of the reticulated interior, and as the reticular fibres have as strong a molecular attraction for these particles as the strands of a cobweb have for dust, on microscopic section after this form of treatment shows practically the full extent of the ink-laden cobweb of reticulum. Instead of dying or staining, we have here succeeded in painting the reticular fibres, which is a rather unusual histological procedure. There is one exceptional region. The ink does not gain entry to the ellipsoids, which therefore remain unpainted. To coat the reticular fibres of these structures we must inject the pigment, not by way of the veins, but by way of the arteries. By what means this sharp barrier is maintained at the surface of the ellipsoids is hard to explain.

### The Reticular Boundaries

Let us now consider the reticular boundaries. When we remember that over and above the fibrillar capsule on which the reticulum must of necessity depend, there are only two major intrusions into the reticulum by the arteries and veins, it is plain that the ultimate boundaries of the reticulum are either capsular or vascular. Suppose we examine the reticulum when it encounters one of the larger arteries or veins. As they enter practically within the sphere of influence of the structure, the interlacing reticular fibres surround it and rapidly merge into it. While the fibres thus enclose their vessels rapidly become smaller and finally in contact with the true fibres. It is said that fibres do not pass of the reticulum, but that reticular fibres have planted themselves into a dark world in which clunk and interlace, virtually unperceived. Up to a certain point the cap penetrates between and slides upon the within of the network, but at finer progress it is to be held by the mere compression of the fibrillar material and just beyond this boundary lies the true thin wall of the vessel. So far noted conditions of the reticulum may be found in any region under the capsule and over the leaves, the vessels under the capsule and at the very part of its boundary surface we might be concluded that the fibrillar material separated from the reticulum, but a minute and constant of those conditions. In any place, however, particularly toward the periphery and around vessels, but also under the capsule, it is evident that but upon the interior of the reticulum, more could be said in the arrangement of the capsule. Yet the derangement between the vessels and the capsule is very small and the reticulum is practically sharp. Where are many strands of reticulum, a fully developed vessel or more often the capsule, the various layers or lights between the anchoring fibres are seen to bring it with blood. In other words, a thin but complete screen of reticulum exists off the capsule and the minute vessels from contact with the splenic blood.

### Two Modes of Arrest of Haemorrhage from a Vessel

In order to appreciate the significance of this arrangement let me address for a moment to you in an experiment which is easily carried out though I have not seen it described. Suppose the carotid artery of a dog has been laid bare with the intention of observing the method of arrest of haemorrhage when the vessel is punctured. If the adventitia is removed before puncturing the artery, the blood sprays out for a very long time. When the haemorrhage eventually ceases the wound is seen to be plugged with a platelet thrombus. Coagulation plays no part here in stopping the bleeding. It is on the other hand the intact vessel is punctured the course of events is totally different. No external bleeding occurs. The blood simply enters the meshes of the adventitia which it distends like a sausage. The bleeding is very soon over. No plugs of platelets has this time formed in the orifice in the media. Arrest is due to the prompt coagulation of the blood in the adventitia. The same experiment may be carried out on the tort of a skate. If the adventitia has been previously removed, the wound is eventually plugged by agglutination of the nucleated spindle cell. If the vessel is punctured through the adventitia prompt coagulation occurs which leads to rapid arrest of haemorrhage.

### Haemothymic and Anaemothymic Tissues

This experiment teaches us that in contact with the fibres of ordinary connective tissue blood undergoes a change being inevitably induced to coagulate. We know that the blood may come freely in contact with reticulum without being induced to clot. In its negative action upon the blood reticulum like ordinary endothelium may be termed *haemothymic*—that is to say these tissues may freely touch blood. By contrast with the *haemothymic* structures probably the great mass of the other tissues of the body and certainly ordinary connective tissue, are *anaemothymic*, these may not touch blood. In the spleen the anaemothymic structures—namely the capsule the blood vessels, the Malpighian corpuscles, which lie in the

adventitial sheaths of the arteries, and the trabeculae—are screened off by means of haemothymic reticulum from the reticular interior.

### Continuity of Reticular and White Fibres

A striking fact is that the reticular fibres are structurally continuous with the fibrillar bundles of collagenous material that form the capsule and the true sheaths of the vessels. For a time I was inclined to think that the distinction between the two kinds of fibres, the anastomosing reticular and the non-branched "reticular" is absolute. Our president Sir Edward Sharpey Schafer had observed in lymphatic glands complete structural continuity of the two kinds. It was difficult at first to confirm this in the spleen, but repeated examination eventually showed that the larger reticular fibres around the vessels and under the capsule directly and abruptly change into fibrillar bundles of the ordinary white connective tissue type. This is not the place to enter into a discussion as to the possibility of an ultimate chemical separation between the two kinds of material. Hitherto no satisfactory chemical differentiation has been made and Mallory has recently shown that the supposedly specific reticular stain fails to differentiate between reticulum and ordinary connective tissue fibres. Suffice it to say that there is a difference of a physicochemical kind which involving the surface properties of the fibres may well lie at the root of their ultimate divergent in features of structural character.

### Function of Endothelium with Reticulum

Our survey of frontiers is not yet wholly complete and the boundary question into which this meeting has temporarily constituted itself has all too obvious problems before it. These being questions of "corridors" and "ports" rather than of land frontiers are of very particular interest and before concluding we must have some decision however provisional regarding these critical regions. The blood is conveyed to the spleen in a conduit of endothelium. It leaves the spleen by a similar conduit. The arterial endothelium creeps inwards to a certain distance and then stops. The venous endothelium of the organ derived from the parent stock of endothelium that lines the chief veins likewise creep inwards as far as it may. Between the two conduits of haemothymic endothelium intervenes the whole irregular sponge of haemothymic reticulum. How a junction of endothelium with reticulum effected at the two terminal station respectively.

I have said that the substance of the ellipsoids consists of very finely meshed reticulum. Their central cavity is lined with endothelium. The junctional station in this case is therefore to be sought in the interior of the ellipsoid and just at the place where the endothelium rests upon the finely meshed reticulum. Although to the eye this endothelium appears to form a complete lining to the central cavity we know that the blood can pour between its constituent cells. May it be that endothelial cells possess a bipolarity as we know them to be and resting upon a haemothymic instead of an anaemothymic tissue have difficulty in obtaining a proper base or foundation for their attachment. Some such supposition that is rendered more likely by a turn from the ellipsoids to consider the venous sinuses which are also endothelium lined. In the spleen of the rat these may be readily studied. They consist of nothing but tabs of endothelium surrounded by the simplest possible reticulum. So far as any special modification of the arrangement of the intervening reticulum goes the venous sinuses might simply be punched out of the general reticulum with a sharp needle. Yet when the inner sinus-directed surface of the reticulum envelops each sinus is examined with a little power innumerable fine brushes of freely ending reticular fibres are found projecting towards the endothelial surface. In turn appears in action to form a complete lining of the sinus. Now we know that blood can pour as easily through the wall of the sinuses as through a sieve. The apparent continuity of the lining endothelium is wholly deceiving and we connect the anomaly of the porosity or the lining with the intrinsic difficulty of attaching endothelial cells to reticular fibres. They are here cemented, not to the haemo-

flagmies sides of the fibres, but to the delicate truncated or amputated ends of the microscopic brushes, which alone can obtain a grip on these pavement cells. Thus at least is my interpretation, conjectural, but I hope reasonable, of what I see.

#### CONCLUSION

In the survey I have elected to deal with one single aspect of the spleen problem. It is true that members of my laboratory in McGill University—Dr M F Cashin, Dr L S Mills, Dr J G P Cleland—have recently been publishing or participating in publishing certain novel findings with regard to the spleen, but as these are already available in printed form I thought it better to branch away from the details of their work and to attempt to express some general ideas which emerge in considering the peculiar architecture of the organ. There has been no time as yet to put these views, in so far as they are hypothetical, to direct experimental test, or otherwise to develop experimentally any of the further issues that forthwith present themselves.

In view of the increased interest in reticular tissue since the introduction by Aschoff of the term "reticulo-endothelial system," may I be permitted to say that, important as the conception of this system is, the name that Aschoff chose for it is rather apt to mislead, for the reticulo-endothelial system is essentially devoid of any endothelium. In view also of a common misconception attaching to the name, it is well to remember that reticulum occurs in many places to which the corpuscular fluids, blood and lymph, have no access, in other words, the presence of reticulum in an organ does not mean that the organ constitutes part of the reticulo-endothelial system. It is true that reticulum, at least as we find it in spleen, bone marrow, and lymph glands, is haemolymphatic, but this may be a macro incident of its constitution, in the same sense as one might say that the excitability of nerve fibres to an external stimulus applied anywhere along their length is a fortuitous rather than a necessary feature of their organization. Should inquiry be made as to the primary function of reticulum is compared, say, with areolar tissue, I should like to make one significant observation. When we examine the various localities in which areolar tissue occurs—for example, between muscle fibres or tendon bundles, under the skin, around nerves, blood vessels, etc.—we find that they are all places where shearing or sliding movements occur. Such movements of slip also occur between serous membranes and in synovial joints. The shearing movements that occur where areolar tissue is found are, however, subject to definite limitation. It is the inextensible white fibres of the tissue that impose a limit on the amount of shearing displacement, the elastic fibres serving the purpose of restoring the structures to the neutral position. Now reticulum constitutes the connective tissue framework of solid glands, such as the kidney, liver, or spleen, where shearing displacements as such are not called for, but where uniform expansile movements must be provided for. According to this conception the primary purpose of reticulum is a mechanical one, its haemolymphatic properties are secondary.

#### DISCUSSION

Professor J BARNETT (Cambridge) reviewed the relation between the nervous system and the vascular function of the spleen. Using the preparation in which by a surgical operation the spleen could be placed outside instead of inside the dog's body, it had been shown that during muscular exercise the discharge of the spleen was controlled by the nervous system. The spleen anticipated exercise, and even expelled its blood into the general circulation when irritated by jealousy or anger. In the case of a jealous animal, the spleen of which had been made to grow outside it like a mushroom, the organ might be seen to grow pale when the animal's liver was fondled. Was this pallor specific to the spleen, or did it affect the whole alimentary tract? The spleen circulated the blood in its pulp: this also seemed to be ruled by the nervous system, for it did not occur in denervated portions of the spleen. The function of the rhythmic contractions of the spleen might be the production of this concentration.

Professor P T HERRING (St Andrews) pointed out the necessity of considering the allied glands, especially haemolymph glands, in investigating the functions of the spleen. He considered the circulation of blood through a lymph gland and mentioned that cells could be taken up from the circulation and held by the reticular cells. These cells became detached and migrated to the centre of the nodule. It was considered that attention should be paid to this aspect in relation to the lymphoid tissue of the spleen.

Sir HUMPHRY ROLLESTON (Cambridge) asked for further information about the data for the existence of two methods of circulation of blood through the spleen—one, perhaps, through the subcapsular area, the blood rapidly leaving the organ, the other of the storage nature, in which the blood remained there until it was wanted. He added that it would be interesting to know about the influence, inhibitory or otherwise, of the spleen on the bone marrow. How far had the spleen any special influence on immunity? Secondary as well as primary growths were very rare in the spleen, the rarity of secondary growths was perhaps partly due to the infection cells being drawn on into the liver, or was there some further power of resisting neoplasia in the spleen?

Dr H C HOU (Peking) reviewed the experimental work in progress in Peking. The spleen was attached to the body wall and divided into halves. The upper portion had an intact nerve and blood supply while the lower half was denervated. A marked reduction in the size of both portions was observed after exercise, the diminution being more pronounced in the denervated segment. It was suggested that this was due to the liberation of adrenaline, as no change had been found in animals where both adrenal bodies had been removed. Spleens of doubly adrenalectomized dogs only contracted to a slight extent after death, while a marked reduction was found in the normal dog. Injections of adrenaline and pituitrin caused diminution in the size of the spleen.

Sir EDWARD SHARPEY-SCHAEFER (Edinburgh) described experiments proving that the spleen was an organ most sensitive to adrenaline.

Sir BERKELEY MOXMEYER (Leeds) remarked that recent investigations by the physiologists had borne out the anticipations of older writers. Pliny had stated that the spleen was enlarged in those who exhibited "immoderate laughter," and MARIN in *Twelfth Night*, calling Sir Toby Belch when he was twitting Malvolio, refers to the same function. In *King John* the Bastard spoke of "spleen of speed to serve Your Majesty." Physiology had been termed a "laggard science." The surgeon evidently seeking for knowledge of many of the functions of the spleen turned almost in vain to the physiologists for answer to such questions as why all the splenic blood passed through the liver, why the veins from the tail of the pancreas carrying blood from the islands of Langerhans conveyed more blood than from the larger end of the gland, and why the blood from the large intestine joined the splenic vein before the blood from the small intestine. In connection with splenic anatomy, many problems needed consideration and answer. The surgeon had shown, by his operations for haemolytic jaundice, one of the functions of the spleen. Sir Berkeley urged that physiologists should make their observations not only upon cats and dogs and mice, but upon men. Their work should be not only in the laboratory, but side by side with physicians and surgeons in the wards and in operating theatres. They would so give a purposeful direction to investigation and fill many gaps in the knowledge of functional anatomy.

Professor TAIT, in his reply, said that lymphoid tissue was not an essential element in the structure of the spleen. At the same time the circulatory and phagocytic arrangements present in the spleen showed a remarkable similarity to those adduced by Professor HERRING as occurring in lymph glands. In the ellipsoids the blood first came into contact with reticulum, and foreign particles tended to adhere to the reticular fibres of these ellipsoids.

The particles were now collected and ingested by the sessile phagocytes of the ellipsoids, which thereafter migrated into the splenic parenchyma, just as the phagocytes of the lymphatic glands travelled when the empty ellipsoids underwent a regenerative process accompanied by hypertrophy. As Dr I. S. Mills had shown, this process might be at the root of splenomegaly. In answer to a criticism by Sir Almoth Wright, who objected to a division of the tissues into haemolymphic and anemolymphic, on the ground that the blood coagulating principles were soluble rather than cellular, he stated that no tissue extract was active unless it contained cellular debris. He referred to recent work by Dr Ekland and himself on the nervous machinery controlling rhythmic contraction

example we may take the case of saponin acting on washed mammalian red cells at a constant temperature.

In such a case it is easy to satisfy one self that the reaction which results in lysis is accompanied by a using up of saponin, and by a combination of the lysin with some component of the red cell envelope. This component is certainly protein in nature. The amount of saponin used up in producing lysis of any given number of cells can be very exactly measured and the rate at which the using up proceeds gives us the rate of the reaction between the lysin and the protein component of the envelope with which it combines. This reaction we call the "fundamental" reaction. The factors upon which its velocity depends have been exactly determined and it is known that the amount of saponin,  $\sigma$ , used in producing lysis in time  $t$ , is given by the expression (1)

$$kt = \log \frac{c}{c-x}$$

where  $c$  is the initial concentration of saponin present in the system, and where  $x$  is a constant which varies with the surface presented by the cells, the temperature, and other factors. The fundamental reaction which is described by this expression with great accuracy, is therefore a reaction of the first order, and its velocity at any moment dependent on the concentration of free lysin present at that moment.

Expression (1) thus gives the quantity of saponin combined with the cells at the end of any given time, but it does not, as it stands, give the amount of lysis which results from this combination. The reason for this is that the cells offer different resistances to the lysin, so that the least resistant cells haemolyse when only a small amount of their protein component is united with the saponin, whereas the more resistant cells require large quantities of the protein component to unite with the lysin before haemolysis takes place. On theoretical grounds we should expect that the cells if grouped according to their resistance, would give a frequency distribution of a symmetrical type, the resistance of a few cells being small, the resistance of a few cells being great and the resistance of the majority being intermediate. This is in fact the case, and the particular distribution for human cells at least, is of the type shown in expression (2)

$$n = y_0 \left(1 - \frac{x}{a}\right)^m$$

Here  $n$  is the number of cells expressed as a percentage of the whole for convenience in any group of resistance  $x$ ,  $y_0$  is the number of cells of mean resistance, and  $a$  and  $m$  are constants.

Now as the fundamental reaction proceeds according to expression (1) quantities of lysin  $x_1, x_2, x_3$ , etc. combine with the cell in times  $t_1, t_2, t_3$ , etc. The cells whose resistance corresponds to  $x_1$  haemolyse when  $x_1$  is formed, and, if we want to determine their number, we can do so by means of expression (2). When  $x_1$  is formed the cells whose resistance corresponds to  $x_2$  haemolyse; this number is again given by expression (2). And so on for  $x_3$  and for all other values of  $x$ . The number of cells which are haemolysed at any moment from the beginning of the reaction until the stage of complete haemolysis is accordingly not to be found from any one expression but from the simultaneous solution of expressions (1) and (2).

The result of this simultaneous solution is an S-shaped curve which gives the number of cells haemolysed at any stage of the experiment and a the fundamental reaction is steadily slowing down the S-shaped curve is always asymmetrical. Recently several methods have been introduced for the study of such curves by far the best being that which depends on the use of selenium as a means of measuring the intensities of the light transmitted by the cell suspension. By this method which we owe to Mellanby it can be shown that the S-shaped curves obtained from experiment agree exactly with those calculated from expressions of the form of expressions (1) and (2). The conclusion must be that the fundamental reaction between the protein of the envelope and the lysin is of the first order and that the resistances of the cells are expressed by a frequency distribution of a Pearson's Type II. That some explanation such as this is the probable one was suggested by Brooks<sup>5</sup> in a theoretical

## THE KINETICS OF THE VARIOUS HAEMOLYTIC SYSTEMS

OR

ERIC PONDER D.Sc. M.B. CH.B. ENR.,  
Lecturer in Physiology, University of Edinburgh

THE object of an opening paper should admittedly be to arrange and to condense the subject so that it can be easily grasped even by those who are unfamiliar with it. In the case of the subject of haemolysis with its many and diverse investigations, this is impossible, I propose, therefore, to fix at the very beginning the point upon which all these investigations must ultimately converge and to deal with the subject by describing certain successive steps which lead up to the final problems for the solution of these final problems, concerned as they are with the reactions occurring in complement-antibody systems, forms the principal justification for the labour spent on the study of simpler haemolytic phenomena. This treatment can only result in the presentation of the subject from a restricted point of view, it will, however, make the connexion between the simple and the complex forms of haemolysis as plain as is possible.

Before considering the action of even the simplest haemolysin it will be as well to be quite clear about the structure of the cell upon which it acts. All the recent investigations lead us to the conclusion that the red cell of mammals is a balloon-like structure possessed of an envelope of considerable strength. One of the clearest proofs of this is the fact that the changes of shape and size which the cell undergoes both in hypotonic solutions and in solutions containing haemolysins, are those of a balloon-like body and not those of a sponge-like structure; if more direct evidence is required Seifriz<sup>2</sup> has actually microdissected the human red cell stretched its envelope and observed the escape of fluid containing haemoglobin. There is considerable evidence, from investigations on quite different lines, that the envelope is composed principally of protein and not of lipid as was once thought in this connexion may be mentioned the work of Oliver and Barnard<sup>3</sup> on cell agglutination of Seifriz on microdissection as well as the results of the recent work on the haemolysins. The best conception of the structure of the envelope is probably one similar to Bechold's—a protein framework, in the interstices of which lipid is contained. Several proteins probably enter into the composition of the framework.

The action of the haemolysins must therefore be principally on this complex envelope, its continuity being destroyed, with the result that the fluid contents are liberated into the surrounding fluid.

### 1 Simple Haemolytic Systems

Setting aside the instances of lysis by mechanical means, which tell us very little, the simplest cases of haemolysis are to be found in systems which contain one lysin of known constitution and in known quantity acting on washed red cells and acting in the absence of any substances which accelerate or inhibit the reaction. As an

A paper read in opening a discussion on haemolysis in the Section of Physiology and Biophysics at the Annual Meeting of the British Medical Association, Edinburgh, 1927. Sir Edward Sharpey-Schafer, M.D. F.R.S., President of the Section, was in the chair.

paper of outstanding importance some six years ago, all the investigations since that time, both theoretical and experimental, have placed this hypothesis in an unassailable position.

From the foregoing we should expect there to be a relation between the quantity of protein in any particular type of red cell and the resistance of that cell to saponin. This relation certainly exists, for if we arrange the cells of different species in order of their resistance to saponin, we find them arranged very nearly in order of their protein content. Unfortunately for simplicity, however, this relation does not appear to hold for other haemolysins. Kofler and Luzzati<sup>6</sup> have shown that the protein content does not determine the resistance to digitonin, senegin, and other glucosides, and McLachlin and I have shown the same absence of the relation in the case of the haemolysins of bacterial origin.<sup>7</sup> Such observations certainly give rise to some little difficulty, but it is to be remembered that the affinity of the protein of the cell for the lysin, as well as the absolute amount of the protein in the cell, has to be taken into account. In the case of saponin, the affinities of the proteins of the cells of the ox, sheep, rabbit, etc., for the lysins are much the same, with the result that the absolute quantity of the protein is the only factor influencing the resistance, in the case of other lysins the affinities may be quite different, perhaps owing to slight differences in grouping within the protein molecule, and thus the effect of the absolute quantity of protein present in the cell envelope may well become of secondary importance. The matter can be decided by a careful evaluation of the constant  $k$  in expression (1), but this is a matter of great difficulty.

By methods identical with those used for the investigation of the haemolytic properties of saponin it can be shown that sodium taurocholate, and also sodium glycocholate in certain concentrations, form compounds with the proteins of the cell envelope, the process of formation of this compound is, in the case of saponin, a reaction of the first order, and is described by an expression of the form of expression (1). The complete solution of the kinetics of the haemolytic reaction involves two expressions just as in the case of saponin, the first relating to the velocity of the fundamental reaction, and the second giving the distribution of the cell resistances. The frequently made statement that the bile salts act as solvents of the lipoids of the red cell envelope and thus produce lysis will not bear even the most superficial examination, it is, for example, quite incompatible with the fact that sodium glycocholate in concentrations of about 1 in 100 is much less haemolytic than the same salt in concentrations of 1 in 1,000.

To the substances which fall into this simplest class of haemolysins may be added most of the haemolytic glucosides (digitonin, senegin, smilacin, sapotoxin, helleborin, etc.), the soaps,<sup>8</sup> and the salts and acids allied to the bile salts. Each of these substances forms loose compounds with protein, and each, when studied quantitatively, will be found to follow the same laws as have been shown to hold for saponin. Sodium glycocholate alone presents peculiarities. Within the last few months McLachlin and I have been able to show that most of the lysins of bacterial origin fall into this class, for the haemolytic substances produced by *B. uelchii*, *B. anthracoides*, *B. tetani*, *B. histolyticus*, *B. subtilis*, *B. coli*, *El Tor vibrio*, *Streptococcus pyogenes*, and *Staphylococcus pyogenes*, all act in a manner similar to saponin, and conform to the same quantitative laws. It is of interest to note that two of these lysins—that of *B. histolyticus* and that of *Streptococcus pyogenes*—are definitely known to be proteolytic.

## 2 Inhibition by Serum

Since, in the case of all the lysins of the saponin class, the reaction which results in haemolysis appears to be one between the lysin and the protein of the cell envelope, we should expect these lysins to unite with other proteins to form non-haemolytic compounds. This can be readily shown to occur, for, if small quantities of serum or plasma are added to the haemolytic systems, inhibition of haemolysis results. This inhibition was first shown by Bayer<sup>9</sup> to be dependent on the presence of serum proteins, although

previously it was believed that it was due to the presence of lecithin or cholesterol. Bayer's observations have been repeatedly confirmed. Recently it has become possible to measure the amount of the lysin which unites with the proteins, and the results indicate that the combination takes place according to the formula applicable to adsorption processes.<sup>10</sup> We therefore conclude that the lysins of the saponin type, which are all surface active, form with the proteins of serum and plasma non-haemolytic adsorption compounds, as the result of which lysin is removed from the system, so that in inhibition of haemolysis results. These observations have been confirmed by Kennedy<sup>11</sup> and by Donnelly and Grime Mitchell<sup>12</sup>; they are in themselves interesting examples of adsorption occurring in colloidal systems, and their full significance from the point of view of haemolytic reactions will appear when we consider the more complex systems. In the case of sodium taurocholate and of the soaps, the non-haemolytic substance which is formed can actually be seen as a fine opalescence which appears on the addition of the serum.

## 3 Cell-Serum-Lysin and Cell-Lysin-Serum Systems

We have now to consider one respect in which haemolytic systems containing sodium taurocholate, sodium glycocholate, or certain of the soaps, differ from systems containing saponin, the glucosides, or the bacterial haemolysins. The serum proteins always inhibit the action of saponin, owing to the formation of a non-haemolytic compound as the result of a combination between the lysin and the proteins, the serum proteins may, on the other hand, either inhibit or accelerate the action of the bile salts, according to the order in which the components of the haemolytic system are mixed together.<sup>13</sup> As an example, let us take 1 ccm of a suspension of washed cells and add first 0.1 ccm of serum, one minute afterwards we add 1 ccm of 1 in 3,000 sodium taurocholate. The result is an inhibition of lysis by the serum. Now we reverse the process, adding to the same quantity of cells the same quantity of lysin, and adding after the same interval of time 0.1 ccm of serum, the components of the system are exactly the same, but the result is not an inhibition, but almost immediate lysis. We have here the interesting case of haemolysis depending not only on the components of the system, but on the order in which these components are brought together. This occurrence introduces into the investigations quite a new type of complexity, and since the two systems which give diametrically opposed results are made up of the same substances in exactly the same quantities, the only way to distinguish between them is to draw attention to the order of the additions, calling the first system, in which there is inhibition, a cell-serum-lysin system, and the second, in which there is acceleration of haemolysis, a cell-lysin-serum system. The order in which the components are mixed thus indicates the order of addition which is necessary.

The inhibition is easy to explain, for it occurs for the same reason as in cell-saponin-serum systems in which the order of addition is immaterial, the proteins of the serum unite with the lysin to form a non-haemolytic compound, and by the formation of this lysin is removed. The explanation of the acceleration, on the other hand, constitutes a most formidable problem, and, indeed, would probably be impossible to obtain were it not for the fact that an almost identical occurrence takes place in systems in which the lysin is one of the haemolytic dyes. To the consideration of these systems we therefore pass.

## 4 The Haemolytic Dyes

Browning and Mackie in 1914,<sup>14</sup> and Mackie in 1919,<sup>15</sup> have described a curious phenomenon occurring in systems containing brilliant green, and to a less extent in systems containing other dyes of the triphenyl-methane group. Brilliant green is itself a haemolytic, but only in high concentrations, in lower concentrations it acts by "sensitizing" the cells, so that the subsequent addition of small quantities of serum produces rapid lysis. The "sensitization" is carried out by mixing washed cells with a dilute solution of brilliant green of about 1 in 50,000. The mixture is allowed to stand for a short time, the cells centrifuged down, and washed till the dye disappears from the super-

nating fluid. The cells are then re-suspended in saline. The addition of about 0.1 c.c. of any normal serum or plasma to these sensitized cells brings about haemolysis in a short time.

The similarity between this phenomenon and that observed when serum is added to cells which have been previously mixed with one of the bile salts will at once be apparent. In each case the lysin brilliant green, or bile salt must first be brought into contact with the cells, and in each case the subsequent addition of normal serum or plasma brings about rapid haemolysis. The similarity is made even more striking by Mackie's observation that, in the case of brilliant green as in the case of the bile salt, it is the serum proteins which are responsible for the reaction, and that if the components of the system are mixed in the reverse order—that is, cells and serum first with subsequent addition of the dye—no haemolysis results. Expressing this more concisely in the cell dye system we get rapid lysis while in the cell serum dye system we get an inhibition of lysis.

The first step in the investigation of this phenomenon is to determine the nature of the "sensitization." So all appearances the sensitized suspension is free from brilliant green, but this appearance is quite deceptive. Large quantities of the dye can be extracted from the cells by the addition of acetone or alcohol, and it is therefore plain that the repeated washings remove only such portions of the dye as is not united to the cells. Further, the portion of the dye which is united to the cells must be united very loosely, for merely warming the suspension of sensitized cells causes a considerable quantity of brilliant green to be liberated into the fluid surrounding the cells. This liberated dye does not appear to be altered in any way and it can be used to sensitize more cells. The "sensitization" thus seems to be nothing more than the formation of a loose compound between the brilliant green and the erythrocytes, so that the dye is present as free lysin in the suspension adsorbed to the cells, and capable of uniting with added serum protein. Quantitative determinations of the amount of dye adsorbed show, moreover, that the union is not with the envelopes alone but also with the contained haemoglobin within the limits of the experimental range the dye taken up is nearly proportional to the amount used in order to bring about the sensitization.

In a case such as this there are no doubt several hypotheses which might be advanced in order to account for the facts. Of these we have to select the simplest and that which is the most in keeping with the explanations which are known to be satisfactory in the case of other haemolytic systems. We therefore assume first that the adsorbed dye combines with the serum proteins of the added serum to produce a lysin which is haemolytic for the sensitized cells. That the brilliant green adsorbed to the cells is certain and that it is capable of uniting with the serum proteins is equally certain, the only obscure point is why the new lysin is either produced only, or effective only when the latter combination takes place after the occurrence of the former.

On this hypothesis the whole of the complex phenomenon can be accounted for. Suppose, to make the matter clear, that one unit of brilliant green is adsorbed to the cells and that this one unit can unite with one unit of serum protein to form one unit of the new lysin. In the circumstances, if one unit of protein is added to the system containing the sensitized cells, the whole of the dye and the whole of the added protein will unite to form one unit of new lysin. This new lysin will produce haemolysis of the cells in a time  $t$  dependent principally on the concentration of new lysin present. Suppose next that only half a unit of protein is added. The whole of the dye will be unable to combine to form new lysin for there is insufficient protein for the combination, as much dye as possible will unite, and half a unit of the new lysin will be formed. This will take a longer time  $t'$  to bring about lysis, for the concentration of the new lysin is only half of that present in the first case. Similarly if we add smaller and smaller quantities of serum smaller and smaller quantities of new lysin will be formed and the time will take longer and longer times  $t''$ ,  $t'''$ , etc., to bring

about lysis. When very small amount of protein are added there may be so little new lysin formed that complete lysis of the cells will never occur, the result is a partial haemolysis, even after long periods of time.

Experiment shows that the above assumptions are in keeping with the facts. As less serum is added, lysis becomes slower the observed time,  $t$ ,  $t'$ ,  $t''$ , etc., corresponding with times which can be calculated from an expression of the form of expression (1). The new lysin, whose concentration is dependent on the quantity of dye which can unite with the added protein according to the law of simple proportions, thus acts as a simple haemolytic the velocity of whose action depends on the concentration present at the moment. In considering the haemolytic reaction in full, the resistance of the cells have, of course to be taken into account, this being done, the entire kinetics of the reaction can be solved in terms of expressions similar to (1) and (2) just as in the case of a simple haemolysin.

So far as the reaction between the brilliant green and the cells is concerned, we can recognize at least two distinct stages. In the first the dye is adsorbed to the cell envelopes and their content still existing as unaltered brilliant green or a free lysin. In the second, which occurs after a long period of time a reaction which results in haemolysis occurs between the adsorbed dye and the cell envelopes. It is essential to note that the union of the dye with the serum protein, and the production of the new lysin which we have been considering occur in the first of the two stages. If we replace the brilliant green by sodium taurocholate we get very similar occurrences taking place the problem is, however, far more complex, because the reaction which results in haemolysis begins immediately the bile salt is added to the cell. There is thus never a stage or "sensitization" at which the reaction can be stopped short, for the taurocholate which is haemolytic by itself, is continually attacking the cell envelopes, with the result that the free lysin in the system is continually decreasing. The amount of free lysin at any moment can, however, be calculated quite easily, so that, if at any moment we add serum, we can say just how much free lysin is present in the system to react with the added protein, as well as the amount of taurocholate which has been transformed as the result of the primary haemolytic reaction. In adding serum, we have therefore to be careful that the extent to which this primary reaction has proceeded is allowed for, so that all additions are made under known conditions. Although this involves an elaborate technique, it leads to results which are capable of explanation. They show that the phenomena observed with the bile salt are identical with those observed with brilliant green, the taurocholate replacing the dye as a "sensitizing agent," although it is haemolytic by itself, the sensitization seems to be due to a loose combination of the bile salt with the cells, and the lysin which follows the addition of serum to the formation of a new lysin as a result of the combined taurocholate uniting with the added proteins. Unless care is taken, however, the reaction is influenced by inhibition phenomena although the nature of the reaction itself is clear the effect of these secondary reactions still needs investigation.

### 5 Cell Complement Silicic Acid Systems

These systems have attracted a great deal of attention since the discovery by Landsteiner and Jagiel<sup>1</sup> that colloidal silicic acid can replace antibody in complement-antibody system. The colloidal silicic acid is best prepared from ethyl silicate, and the complement used should be that contained in guinea pig serum after removal of the native haemolysins. As there is no specificity attached to the reaction, any type of red cell can be employed.

In one respect at least these systems resemble those already considered for the velocity of the haemolytic reaction depends on the order in which the components of the system are brought together. The complement should be added to the cells first, and the two allowed to stand for a short time, the subsequent addition of silicic acid then brings about a rapid lysis. The following remarks apply only to systems in which this order of mixing is observed.

The most interesting point in connexion with these systems is the way in which the velocity of the haemolysis

varies with the quantity of complement and of silicic acid. Adding a constant amount of silicic acid, which is non-haemolytic by itself, to systems containing an increasing amount of complement, we get increasingly rapid lysis until a certain maximum is reached, with greater amounts of complement, however, the lysis becomes slower once more, until finally there is no haemolysis at all. There is thus, for every quantity of silicic acid, one particular quantity of complement which gives a maximum velocity of lysis, quantities greater or less than this give less rapid lysis, or none at all.

These maxima possess a special property which greatly simplifies the kinetics of the systems, for the ratio of complement to silicic acid at any maximum is always constant. For example if with 0.5 ccm of silicic acid we need 0.2 ccm of complement to give a maximum, we shall require 0.1 ccm of complement with 0.25 ccm of silicic acid, or 0.02 ccm of complement to give a maximum with 0.05 ccm of silicic acid. But the most remarkable point of all is that when complement and silicic acid are added in this ratio which gives the maximum lysis proceeds as if the lysis were a simple haemolysis. The kinetics of the system become capable of expression in terms of expressions (1) and (2), and all complexity seems to have disappeared. So far as this evidence is concerned, we are therefore justified in assuming that the complement and the silicic acid unite to form a simple haemolysin, provided that they are present in certain proportions.

Too much complement on the one hand, or too much silicic acid on the other, results in a haemolysis slower than at the maximum. In such systems the kinetics have still to be reduced to simple laws. We know, however, that the slower lysis is the result of a reaction very like the inhibition of a simple lysis by serum. Suppose, for instance, that the ratio for the maximum is one unit of complement to one unit of silicic acid. If we add to one unit of complement three units of silicic acid, two of the added units cannot combine to form the lysis, as there is insufficient complement, these two units act as an adsorbent, ready to adsorb and to render inactive the lysis as it is formed. Excess of complement acts in the same way, for the proteins in the complement-containing serum are scarcely inferior to colloidal silicic acid as an adsorbent, only when there is no excess of either component is the newly formed lysis free to act without inhibition.

This completes the account of the problems which connect the simplest haemolytic systems with the most complex, for the next step in order of complexity is the problem of the kinetics of the complement-anticoceptor systems themselves. In general, these systems are similar to cell-complement-silicic acid systems, they are, indeed, in some respects even less complex, for the inhibition phenomenon is less marked. They can be investigated by the same methods as are applicable to the simpler haemolyses, and their complete elucidation is only a matter of time.

As a review of what is known about haemolysis in general this account is very incomplete. All consideration of haemolysis by hypotonic saline, cobra venom, and ultra-violet light is omitted, no mention has been made of the results of the investigations into the changes of form which the cells undergo during lysis, nor is there any reference to the effects of salts, sugars, and other such substances on the action of the various haemolysins. The necessary degree of compression precludes even the description of the essentials of the technique employed. The paper therefore gives quite an inadequate idea of the weight of the evidence on which the conclusions are based, and accordingly the reader may be left with the impression that some of the explanations offered are rather too simple to be true. It is to be remembered, however, that the almost notorious complexity of most of the less simple haemolytic systems is very largely the result of investigation by methods which are often faulty in themselves and which are never strictly quantitative. It is only when technique is rigidly standardized, and when every variable is subjected to exact measurement, that the apparent complexity disappears.

## DISCUSSION

Professor J. MELLANBY discussed the action of enzymes on the red blood corpuscles. He pointed out that the cell envelope could not be acted upon by either trypsin or lipase. Haemoglobin was found to be digested by enzymes, and there was, therefore, evidence that a protective layer or envelope existed which protected the haemoglobin. It was shown that at the end of haemolysis the anticoceptor disappeared while the complement was still present in an intact form. The speaker stated that probably in the Wassermann test the complement was precipitated by the syphilitic substance in the presence of the antigen.

Mr E. SHAMPEL-SCHARRER questioned the reversal changes described.

Dr ERIC PONDIN, in reply, said that in his opinion there was no fundamental difference between the kinetics of the complement-anticoceptor system, and of silicic acid and simple lysins.

## THE PLACE OF BISMUTH IN THE TREATMENT OF SYPHILIS

BY

DAVID LILES, D.S.O., M.B., F.R.C.S.F.,  
Lecturer on Venereal Diseases, University of Edinburgh

DURIĆ (1921) SZVERCO and LEONARDI were able to prove that experimental syphilis in rabbits could be treated successfully with a bismuth preparation. In the following year the same workers, and Fournier and Guenot, submitted a series of cases of human syphilis to treatment with a salt of bismuth, and found that the active signs of disease disappeared rapidly, and that this drug appeared to be able to exercise a favourable influence, at least in the earlier cases, on the serological reactions of the blood. Subsequent to the publication of this work in France bismuth and its salts came into general use, and bismuth is now accepted as one of the few drugs which can favourably influence the progress of syphilitic infection.

In considering the place of any drug in the treatment of syphilis it is essential to take into consideration the value of that drug as compared with existing and well known therapeutic remedies, and to review our present knowledge as to—

- (a) The effect of bismuth on the *Spirochaeta pallida* in vivo.
- (b) Its effect on the surface lesions of syphilis in all stages.
- (c) Its effect on the serological reactions in all stages of syphilis.
- (d) Its effect on the general health of the patient.
- (e) The toxicity of bismuth and the immediate or remote side effects to which it may possibly give rise.
- (f) The permanency of the results obtained by its use.

In the limited time available I propose to give a short summary of the observations which it has been possible to make during an extensive clinical experience of the use of this drug in over 6,000 cases of syphilis. The number of injections of bismuth given in this series was over 100,000. In some of the cases bismuth was the only drug used, in others it was used in combination with drugs of the arsenobenzol series and with trypanamide, in others it was administered with mercury and some form of iodide.

\* A paper read in opening a discussion on this subject in the Section of Venereal Diseases at the Annual Meeting of the British Medical Association at Edinburgh. Mr Liles was President of the Section.

Among the many bismuth preparations which are available the following have been used: (1) soluble preparations, (2) insoluble preparations suspended in oil, (3) insoluble preparations suspended in glucose or water. Different preparations from each of these groups, and especially from the latter, have been used, and, from practical experience, the preparation which gives the most consistently good results with the least likelihood of upset to the patient is one of insoluble bismuth in a very fine suspension in isotonic glucose solution. It should contain a high percentage of bismuth, and the drug should, in our opinion, be given intramuscularly.

#### The Action of Bismuth in Destroying the *Spirillum pallidum*

When a therapeutic dose of bismuth is administered intramuscularly to a patient suffering from a primary chancre or a secondary rash in which the *Spirillum pallidum* has been demonstrated, the organism is not destroyed so rapidly as it is when a therapeutic dose of one of the arsenobenzols is given either intravenously or intramuscularly. After an arsenobenzol product is administered one can rarely find a living spirochete in the surface lesion twenty-four hours later, whereas after a potent therapeutic dose of almost any bismuth preparation, spirochetes can not infrequently be demonstrated for three or four days subsequently. From this we may assume that bismuth does not act so rapidly in reducing the contagion of syphilis. This slowness of action is not due to the slower absorption because the bismuth is administered intramuscularly. We have had the same experience when comparing the effect of an intramuscular injection of sulpharsenol with that of an intramuscular injection of bismuth. We have noted the same slowness of action after the intravenous injection of colloidal bismuth.

#### The Effect of Bismuth on the Surface Lesions of Syphilis in all Stages

The continued administration of bismuth intramuscularly causes the primary sore, the surface skin lesions, and the later gunnathous manifestations to disappear rapidly, and in this respect bismuth is almost as efficient as the salvarsan preparations. It is much more rapid in its action on these signs of active syphilis than any of the mercurial preparations. In this respect it would seem to be almost the equal of and occasionally superior to, the arsenical drugs. In three cases which were seen by the author, all of which were in the nature of hypertrophic papular syphilides of a recurrent type, the administration of bismuth rapidly cleared up the eruption when arsenic in one case, and arsenic and mercury in combination in the two others, had previously failed to do so.

The first patient, a case of primary syphilis with a strong positive Wassermann reaction, had been treated by a complete course of novarsenobillon totalling 4.5 grms in a period of eight weeks. Three weeks later a papular syphilide appeared on the face. A second course of 360 grams of novars nobillon was administered in the succeeding even weeks and one month later the papules again recurred. Bismuth was administered intramuscularly and after three injections of hypodermic bismuth the papules disappeared and have not recurred since. The bismuth treatment was continued in this case for close on two years and the patient has been under observation for over eighteen months since. There has been no recurrence of any clinical sign of syphilis and the Wassermann test has been consistently negative for over two years.

In the second case, one of early generalized syphilis, the patient had had a course of injections of neobarsavan and simultaneously mercury being given by the mouth. The total amount of neobarsavan administered in eight weeks was 465 grams. Six weeks subsequent to this course a papular syphilide appeared at the angles of the mouth and nose. Bismuth was administered and the patient apart from appropriate interval of rest has now been under treatment with bismuth and iodides for two years. There has been no recurrence of the clinical signs, the blood Wassermann after two courses of bismuth became negative and has continued negative up to the present.

The third case is even more striking.

A patient with a primary sore of ten days' duration and a weak positive Wassermann test was treated during the first three months with novarsavan and mercury (grey oil) 4.5 grams of the former intravenously and 1 gram of the latter intramuscularly. Some three to four weeks after this treatment a cruminate syphilide appeared on the forehead and palmar and plantar syphilides on the hands and feet. A second intravenous course

consisting of 4 grams of novars nobillon and an intramuscular course of 8 grams of mercury (grey oil) was administered. It failed to influence the skin eruptions. Intramine and colloidal iodine were then given in the former intramuscularly and the latter intravenously in large doses. This was followed by a course of intramuscular injections of grey oil, the total quantity given being equivalent to 16 grams of metallic mercury. Potassium iodine was also given in large doses (23 grain (three drachms)) by the mouth. As this course of treatment failed to influence the syphilides, after which an was administered in weekly injections to a total of 3 grms in eight weeks. The syphilides disappeared temporarily during this treatment but recurred six weeks later. First in the palms and feet, then in the face, and finally in the trunk, a second course of 4 grms of novars nobillon was injected and this was followed by a course of novars nobillon and mercury. There was no sign of syphilis for three months after this, but after the plantar syphilides reappeared and also a recurrent papulo-erosive syphilide on the forehead and on the extensor aspect of one elbow. Bismuth was now exhibited and four courses totalling about 15 grams of metallic bismuth were given in the following year. After the third injection of bismuth in the first course the signs of syphilis on the skin completely disappeared and they have not recurred since. The blood Wassermann reaction became negative after the first course of 4 grams of bismuth and has remained negative since. The patient has been under observation for close on two years without treatment and has had no recurrence of any sign of syphilis and the blood Wassermann and cerebro-spinal fluid has remained negative throughout.

While these may be isolated cases they are impressive, and there are undoubtedly certain cases of syphilis in which the surface signs react extremely well to bismuth, and better than they do to salvarsan and its derivatives.

#### The Effect of Bismuth on the Serological Reactions in all Stages of Syphilis

If bismuth is administered to any case of syphilis before the Wassermann test has become positive, and if the Wassermann test taken again seven days subsequent to the first injection, is still negative (sero-negative syphilis), it is our experience that very few of these cases, if the bismuth treatment is persevered with, will ever develop a positive reaction in the blood. One or two of our cases, however, have developed positive reactions when so treated and Parnell has quoted similar cases. In all the cases in which this has occurred the second test taken within a week after the first treatment showed a weak positive reaction. It is our experience that the development of a positive reaction in a case of sero-negative syphilis treated with the arsenobenzols is extremely rare. Bismuth, therefore, would not seem to be so potent as the arsenobenzols in making certain that a sero-negative case does not become sero-positive.

When comparing the effect of bismuth with that of the arsenobenzols on the reactions of sero-positive syphilis in the primary and early generalization stages, as assessed by the Wassermann test taken at least one month after a course of treatment, the percentage of negative findings after bismuth is not, in our opinion, so large as with the arsenicals. It is certainly much inferior to that obtained when salvarsan and bismuth or salvarsan and mercury are administered concurrently. In late syphilis and latent syphilis it is difficult to estimate comparatively the effect of bismuth and salvarsan respectively on the Wassermann test. Both are successful in a considerable number of cases, while in others both fail to render it negative. In cases in which we have failed to influence the Wassermann test by combinations of salvarsan and mercury or salvarsan and iodides, bismuth also has failed, and we have not as yet been able to find any drug or combination of drugs which will permanently influence certain cases with resistant Wassermann reactions. It is our experience that bismuth is rather more potent than is the intravenous injection of the arsenicals in altering some of the pathological reactions in the cerebro-spinal fluid in certain types of case.

#### The Effect of Bismuth on the General Health of the Patient

When bismuth is given in therapeutic doses it appears to influence the patient's general health beneficially and especially so if before and during the time of its administration the hygiene of the mouth is attended to. The arsenobenzols also have a tonic action, but it is our experience that old and debilitated patients tolerate bismuth in appropriate doses rather better than they tolerate the arsenobenzols. In cases which have shown

themselves sensitive to the arsenobenzols, bismuth is often well tolerated and greatly benefits the health of the patient. It does not appear to be so depressing in its action as mercury, and there is not the same tendency on the part of the patient to lose weight when under bismuth treatment as when mercury is being administered.

#### *The Toxicity of Bismuth and its Immediate and Remote Side-Effects*

In therapeutic doses bismuth gives rise to remarkably few toxic symptoms if the technique of its administration is good. There is practically no pain subsequent to its administration such as there is subsequent to the intramuscular administration of mercury, and there is certainly less discomfort than there is with the intramuscular administration of arsenicals such as sulpharsenal or kharsulphim. The main toxic condition to which it gives rise is stomatitis. This can be obviated by careful cleansing of the mouth and care of the teeth. When it does arise it is not so severe as is the stomatitis set up by mercury. It can be rapidly controlled and ameliorated by the administration of sodium thiosulphate and by oral hygiene. Other toxic effects of bismuth are albuminuria, urticarial eruptions, mild erythema, and loss of weight. If ordinary care is exercised in the administration of the drug, and if appropriate intervals are allowed between successive doses, these complications are rare when metallic bismuth is used. Bismuth, in fact, can be given with advantage to many cases of nephritis and to many delirious patients who would not tolerate the arsenobenzols. In general, it is a much less toxic drug than the arsenobenzols and less toxic than mercury. If care is taken that none of the drug is introduced into a vein there are practically no immediate side-effects in the great majority of cases. It does not seem to damage the liver to the same extent as do the arsenobenzols, nor the kidneys to the same extent as mercury, and rarely if ever is an injection of it followed by a Herxheimer reaction.

#### *Permanence of the Results of Bismuth Treatment*

We have referred to the fact that cases of sero-negative syphilis may not always remain so while under treatment with bismuth alone, but there are undoubtedly other cases of established syphilis which have been cured both clinically and serologically by bismuth alone, and have remained so over periods up to three years. The period during which treatment by bismuth alone has been observed in most cases is as yet too short to enable us to state definitely that its results are permanent, and, in addition, there is up to now no general agreement as to what is the requisite amount of the drug to administer so as to ensure permanent negative serological tests and a complete cure.

The therapeutic power of bismuth compounds in comparison with that of the salvarsin group of drugs when each is used alone may be recapitulated as follows:

Bismuth does not so rapidly kill spirochetes in the early contagious stages of syphilis, and therefore does not so rapidly reduce contagion.

Bismuth has almost as rapid an effect as the salvarsin derivatives in clearing up the surface manifestations of syphilis in all stages of the disease.

Bismuth is less likely to cause intolerance and side-effects, especially in debilitated patients, and in general its intramuscular administration is followed by less constitutional upset than is the intravenous or intramuscular administration of the arsenicals.

Bismuth does not so certainly control the Wassermann and flocculation tests as do the arsenicals, although there are cases in which it very favorably influences these serological tests when other drugs have failed to do so.

When we compare the effect of bismuth with that of mercury when each is administered alone, the evidence is undoubtedly strong that of the two bismuth is the more potent drug in syphilis both in its effect on the surface lesions and on the serological tests. Bismuth kills the surface spirochetes and heals up the skin manifestations more rapidly than mercury; there is less pain after its intramuscular administration and it is followed by fewer signs of intolerance; it has a more rapid action than mercury on the blood Wassermann and other tests. In

therapeutic efficiency bismuth seems to approximate much more closely to the arsenobenzols than mercury when these drugs are exhibited alone in any given case of syphilis.

#### *The Use of Bismuth in Combination with other Drugs*

For a long time we have held the opinion that in the treatment of syphilis in all its stages, with the possible exception of cases of pregnancy, it is advisable to administer conjointly both arsenic and mercury in preference to either alone. Since the introduction of bismuth we have come to the same conclusion with regard to it, and we are firmly of opinion that with few exceptions the joint administration of arsenic and bismuth is preferable to that of either alone. The joint administration of these drugs is comparatively safe, it is well tolerated, and the results in the large majority of cases so treated are highly satisfactory. It is impossible to deny that the therapeutic results following the joint administration of arsenic and mercury were very good, and especially so if the mercurial drug was administered intramuscularly, so as to ensure certainty and accuracy of dosage. The joint administration of arsenic and bismuth has, in our experience, given slightly better results. There is, however, the great advantage from this latter combination that there is practically no discomfort or pain following the intramuscular injections of bismuth and, if due precautions are taken as to the teeth and as to the technique of administration, no intolerance is set up such as occasionally follows the joint arsenic and mercurial treatment. The fact that bismuth is being administered to any given case is not, in our opinion, a reason for lessening the amount of the arsenical drug, and even with the dual therapy there are still some cases of resistant syphilis which we slow to react favorably, although seen and treated intensively at a fairly early period of the infection.

If at any time a rest from either drug is considered advisable, iodides may be substituted, and can be given alike with either arsenic or bismuth.

In several cases we have tried the effect of giving bismuth in combination with mercury, the latter in such cases being given intravenously as mercury oxide. The two drugs do not, in our opinion, go well together. These two drugs are not dissimilar in their action, and they give rise to toxic effects on the same structures of the body. Their joint administration is apt to lead to depression, loss of weight, neuritic symptoms, and to stomatitis. In any cases which showed a very resistant positive Wassermann test we have not been able to influence it permanently by this combination any more effectually than by other and safer methods of treatment.

#### *Tolerance of the Patient to the Various Drugs when*

##### *Administered over Long-continued Periods*

With the arsenobenzols great care must be taken to avoid too intensive treatment over long periods, because of the risk of cumulative effect and the possible onset of such conditions as pruritus and exfoliating dermatitis. In long-continued mercurial treatment stomatitis, diarrhoea, and albuminuria are not infrequent, and the discomfort following on intramuscular therapy by mercury is against its long-continued use. Bismuth can be given over long periods without pain and with comparative safety.

In bismuth therapy there is no complication of any importance which cannot be easily counteracted or controlled. So far as safety of administration is concerned, we are of opinion that either alone, or in combination with an arsenical or iodide drug, bismuth can be given over long periods with comparative comfort and safety.

#### *Combination of Drugs and their Influence in Preventing Neurosyphilis*

There is considerable evidence to show a general consensus of opinion, that the joint administration of arsenic and mercury is superior to that of an arsenical drug alone especially in the prevention of the later manifestations of syphilis. So far as the combination of arsenic and bismuth is concerned, it is our opinion that the joint administration of these drugs is superior in its action to that of either alone, especially in early cases of syphilis. It is too early as yet to make a dogmatic statement on the

subject but we are inclined to the opinion that the two drugs if given together in every case of early syphilis will tend to prevent the later manifestations of syphilis just as does the joint administration of arsenic and mercury.

As regards the comparative therapeutic efficiency of the two combinations we are not as yet in a position to judge. In our own cases the end results are almost similar if viewed from the standpoint of the disappearance of the symptoms and signs of disease. If judged from the standpoint of their effect on the Wassermann reaction there is not a very little difference in the results. Where they differ most is in the fact that the combination of arsenic and bismuth is better tolerated by the individual patient, is followed by fewer signs of intolerance, and gives rise to less pain and discomfort.

This latter effect alone is of very considerable importance in hospital work, in that patients are very likely to continue under treatment for long periods. There have been very few published statistics of the comparative effect of the two combinations, and those of Smechula of Hanover published in the *Klinische Wochenschrift* of July 30th, 1925, are interesting. He selected two series of 100 cases, as his criterion for comparison he compared the efficiency of arsenic and mercury salivate with that of neosalvarsan and bismuth. His findings were that neosalvarsan and bismuth was superior in their action in secondary syphilis and all more so in their rapidity in changing a positive to a negative Wassermann test in latent cases. He was of opinion, however, that the administration of neosalvarsan and bismuth was followed by fewer relapses than that of neosalvarsan and mercury.

Our observations on the comparison of cases so treated do not agree with those of Smechula. We are of opinion that arsenic and bismuth jointly administered influence secondary lesions rather more rapidly than arsenic and mercury. Arsenic and bismuth in our experience has also produced a negative Wassermann test in latent syphilis more often than arsenic and mercury. We agree with him that there are very few relapses met with if either arsenic and bismuth or arsenic and mercury are used but this is more dependent on the long continuity of the treatment than on the combination used. The combination of arsenic and bismuth is, we think, much more efficacious in many cases of neurosyphilis than is that of arsenic and mercury.

In their enthusiasm over bismuth several workers have discarded not only mercury but also the arsenicals in the treatment of syphilis. This is to be deprecated, and especially so in early and congenital syphilis. Arsenical medication is undoubtedly our most efficient method of dealing with syphilis and rendering it rapidly non-contagious, and it cannot be removed from its place of pride by bismuth. Mercury also has still a place in the medication but must give way to bismuth for routine use since it is less well tolerated in that its administration causes rather more discomfort, it is moreover slower in its action in killing spirochaetes in healing the surface lesions and in its effect on the Wassermann test.

The arguments on which the superiority of bismuth to salvarsan rest are based solely on isolated cases of which most of us have had experience, and of which I have quoted three. There is no doubt that bismuth is an extremely valuable drug and that its discovery as an efficient therapeutic agent in syphilis must be regarded as one of the most important developments of therapy during the last few years. We must not, however, allow our enthusiasm over its effects in isolated cases to outrun our discretion and make us lose sight of its deficiencies and of its inferiority to the salvarsan derivatives. What can be said of bismuth is that it is a very valuable addition to the treatment of syphilis, and especially if it is used in combination with the arsenobenzols. It is particularly effective and safe in most of the cases which show a tolerance to the arsenicals and to mercury. In cases which are proving resistant to arsenic or mercury it not infrequently gives brilliant results in causing the disappearance of the specific lesions. In some cases of neurosyphilis and congenital syphilis it apparently gives better results in clearing up the symptoms and signs of disease than either arsenic or

mercury. It is undoubtedly also a safer method of treatment in some of the debilitated subjects who suffer from syphilis such as cases of cardiovascular and visceral syphilitic disease.

It is important in our view that in every case of syphilis in its earlier stages a combination of either arsenic and bismuth or arsenic and mercury, should be given, and that this combination should be continued up to the point of tolerance until both the clinical and the serological manifestations are cleared up. In the subsequent period of treatment we are of opinion that both drugs should still be continued but the amount of the arsenical drug now then be conveniently lessened with a view to avoiding intolerance. The advent of bismuth may in the course of time enable us to learn the quantity of the joint therapy which is necessary to control and possibly cure syphilis but as yet there is far too little evidence of the actual permanence of the results obtained to justify anyone in relying too much on the drug which cures of syphilis should remain under active treatment and observation.

Bismuth in therapeutic doses even in large doses over very long periods without any very noticeable weakening the patient to the same extent as mercury does, and fact alone renders it of very considerable value in the treatment of resistant cases of infection and of old and debilitated patients.

If we were to summarize the present place of bismuth in the therapy of syphilis we could be justified in coming to the following conclusions:

1. Bismuth is an actinotissipulative agent and is more rapid in its destructive action on the *Spirochaeta pallida* than mercury; it is not so rapid as the salvarsan group of drugs in this respect.
2. Bismuth influences the surface lesions of syphilis as rapidly as the arsenobenzols, and more rapidly than mercury.
3. Bismuth with few exceptions is less active than the arsenobenzols in influencing the Wassermann test but is more active than mercury in this respect.
4. The combined administration of bismuth and arsenic is more potent than either drug alone and is free from danger if given in therapeutic doses. The same holds good of arsenic and mercury.
5. The administration of metallic bismuth in a tonic glucose solution is remarkably free from pain and side-effect, and in this respect is better tolerated than either arsenic or mercury.
6. Bismuth is a very valuable drug in cases of syphilis which are intolerant to treatment by arsenic or mercury.
7. Bismuth is a very valuable drug in the treatment of any patient who has advanced organic disease whether the latter is due to or is intercurrent with the syphilis.
8. The intramuscular injection of an insoluble compound of bismuth gives better therapeutic result with less risk of toxic effects than other methods of administering it such as the intravenous administration of colloidal bismuth or the intramuscular injection of the salts of bismuth.
9. The addition of bismuth and its salts to the other available methods of treatment does not as yet justify anyone in lessening the length of time over which every case of syphilis should be treated and kept under observation.
10. Apart from cases of intolerance to other drugs, bismuth is only an adjuvant to the treatment of syphilis and should not be used alone even in the very earliest cases of infection.

#### DISCUSSION

Dr. J. C. BRADLEY (Nottingham) considered the introduction of bismuth of importance only to that of salvarsan. He expressed opinionistic views as to the prognosis in early cases of syphilis and thought that nearly all could be cured by a properly conducted dual therapy. He had found bismuth particularly useful in patients who were intolerant of arsenic and only in interstitial keratitis was mercury more valuable than bismuth. It was not justifiable to give bismuth alone in early cases of syphilis, but it should be combined with arsenic. The dose he gave

of bismuth was 0.2 gram daily. He asked whether the blue line on the gums, a common concomitant of bismuth therapy, contraindicated the continuance of the treatment.

Dr MARY MACNICOL (Edinburgh) said that she had been using bismuth now for three years as an adjunct of arsenic, and thought it more valuable than mercury. In those cases which, although reacting well clinically to arsenical treatment, persisted in giving a positive Wassermann reaction, bismuth had often succeeded in reducing the reaction. She quoted two cases in illustration of this, and referred to its utility in old tertiary cases of gummatous. She had found the drug very useful in cases of intolerance to arsenic, and had not met any case intolerant to bismuth, and only one in which there was stomatitis. In congenital cases she had also been able to obtain negative Wassermann reactions. Intellectually, however, she had found arsenic and mercury better than arsenic and bismuth in very bad congenital syphilis, but bismuth had the great advantage of being painless. She also found it convenient to give arsenic by the mouth during a course of bismuth, it still acted as a tonic and obviated the continual hypodermic injection which many women disliked.

Dr E. T. BURKE (Manchester) placed bismuth just second to arsenobenzol as an antisyphilitic, but much higher than mercury, he said it must be realized that bismuth was a reinforcement and not a substitute for arsenobenzol. He was in favour of bismuth being given alternately with arsenobenzol—not concurrently. He thought that the experiments of Lelhoff-Wyld to show that the therapeutic action of arsenobenzol was enhanced by the presence of another metal in the blood were very unconvincing. Personally he believed that when two highly treponemocidal drugs were used simultaneously either the tissues of the patient would refuse to react properly or the treponema would become resistant. He thought that the practice of concurrent administration was the cause of many persistent positive Wassermann reactions. He was now able to convert many of these into negative reactions by means of potassium iodide followed by metallic bismuth. Arsenic and bismuth might have an actual neutralizing effect on one another. Cases treated with histoval—a bismuth and arsenic combination—gave extremely disappointing serological results. If, as Kolle held, bismuth merely kept syphilis latent, the concurrent administration of the two elements might be very harmful. Bismuth was particularly useful in syphilitic lesions of the circulatory mechanism, in cases of coronary and aortic disease it was safest to rely on it, possibly to the exclusion of arsenobenzol. In the newly born syphilitic child carrying an enormous burden of treponemata he also began always with bismuth. One of its greatest uses was in interstitial keratitis, he only administered arsenic after the eye condition had cleared up. He thought that the best method of administering the drug was in the metallic form suspended in glucose and injected intramuscularly, the intravenous injection of any bismuth salt was dangerous.

Dr W. R. SPOONER (Glasgow) considered that metallic bismuth in isotonic glucose solution was the most satisfactory preparation. Up to the present the quantity of a standard bismuth preparation necessary to effect and maintain a clinical and serological cure had not been established.

Colonel L. W. HARRISON (London) drew attention to the work of Collard and Lucas, who formed a depot of bismuth in a rabbit's ear and then attempted to inoculate it with syphilis. So long as the depot was there no chancre was produced, but as soon as the depot was excised the chancre appeared showing that the bismuth had only kept the syphilis latent. As regards the effect on the Wassermann reaction he thought there was but little difference between the effect of bismuth in combination with arsenic or mercury in combination with arsenic. He had found bismuth particularly useful in myocarditis, sometimes in conjunction with very small doses of sulfarsenol. The toxic effects of bismuth had not proved very severe, but he had

had occasional complaints of rheumatic aches and pains and also of colitis, and he had known dermatitis to be produced.

Dr STORFORD TAYLOR (Liverpool) described a severe case of toxic reaction due to bismuth. The patient had suffered from abdominal pain, sickness, diarrhoea, a mercurial rash, and gingivitis. He also recommended sulfarsenol in very small doses for eridmic cases.

Mr LEE, in reply, agreed that bismuth alone should not be used in early cases. He did not regard the appearance of the blue line on the gums as a contraindication to the continuance of bismuth, but merely as an indication for dental attention. The principal contraindication to further treatment was loss of weight. Bismuth was exceedingly well tolerated as a rule, unlike mercury it never produced nodules. It was painless, and very useful in cases of patient women before starting arsenical treatment. It was also particularly useful in cases which were clinically syphilis but serologically negative. He considered that theunction and oral administration of bismuth were far inferior to injection. He did not agree that the joint and simultaneous administration of arsenic and bismuth and of arsenic and mercury reduced the bodily resistance of patients, though theoretically it might possibly be expected to do so. Myocardial cases, in his opinion, were the only ones in which bismuth should be used alone, in other cardio-vascular patients it should be combined with sulfarsenol. He found it difficult to explain the cases of dermatitis. Some of the cases of gross intolerance he thought might be due to a slight embolism, a small quantity of the metal finding its way into a vein during injection.

### THE EMPLOYMENT OF "POLAR-BODY" DEVELOPING STRAINS OF THE GONOCOCCUS IN TREAT- MENT OF GONOCOCCAL INFECTION \*

BY

MAJOR E. C. LANBURN, D.S.O., R.A.M.C.,

A.I.D.

MAJOR LYN DIVOND, R.A.M.C.,  
Royal Herbert Hospital, Woolwich

For the last two years, at the Royal Herbert Hospital, Woolwich, we have been endeavouring to elaborate a line of treatment of gonorrhoea in the male by intensive immunizing methods. Preliminary reports of this work have already appeared in the *British Journal of Venereal Diseases* for January, 1927, and in the *R.I.M.C. Journal* for 1st March. For the present report we cannot claim any degree of finality, our researches are continuing and our methods constantly changing.

The treatment of gonorrhoea at Woolwich aims at—  
(1) Raising the immunity of the mucosa through which the organism enters the body. (2) Raising the resistance of the particular glands and organs susceptible to attack by the gonococcus. (3) Raising the antibacterial properties of the blood and tissue fluids in order to minimize the risk of systemic spread of the infection. (4) Bringing the patient under certain precise biochemical and colloid-chemical conditions which have been found to give optimum results as regards defence against the invading organism, and placing the infecting organism under conditions in which it is least able to withstand the defence mechanism of the body. (5) Providing a means of determining whether any local foci of the disease remain or whether the patient is completely freed from the infecting organism—in short, to provide a "test of cure."

These objectives have been sought in the following ways—  
(1) Thorough drainage of the whole urethra by mild irrigating fluids. (2) The maintenance of the patient's urine reaction at a pH of 7.2 to 7.4. (3) The intramucosal instillation of a product of gonococcus metabolism which may be referred to as "exotoxin." (4) The proctural

\* A paper read in opening a discussion on this subject in the Section of Venereal Diseases at the Annual Meeting of the British Medical Association at Edinburgh.

administration of this "exotoxin" (5) The instillation into the urethra of another gonococcus product which we call "endotoxin"

#### Drainage

The procedure advocated is the posterior irrigant method. The most efficient drainage is obtained by educating patients to irrigate in this way. The irrigating fluid is potassium permanganate (1 in 20 000 strength) which is the least irritating to the mucous membrane. No bactericidal or astringent action is desired. All that is expected from irrigation of the urethra is drainage and cleanliness and as a consequence, probably a more intimate and prolonged contact of the intraurethral vaccine preparation with the affected mucous membrane. The results obtained without irrigating methods were poor and we were compelled to fall back on routine irrigations.

It is not easy to carry out perfect irrigating method in the acute stages of the disease but the time and trouble spent in educating patients to irrigate efficiently is well repaid by result and as our vaccine method becomes more efficient we find that it is only when patients cannot be induced to irrigate efficiently that results are disappointing.

#### The Hydrogen Ion Concentration of the Urine

The body's optimum response to the attack of the gonococcus occurs when the hydrogen ion concentration of the urine is within the limits of pH 7.2 to 7.4. Within these limits phagocytosis is at its maximum and the gonococcus is almost invariably placed to withstand the attack of the body cells and fluid. Below this reaction on the acid side conditions favour the gonococcus phagocytosis is at a minimum and the invading organism surrounded by a tough capsule of sclero-protein, is in its most resistant form.

With an alkaline reaction there is a tendency to auto-lolysis of the gonococcus with liberation of toxic "endotoxin" which has an irritating and provocative effect on the body. In practice we endeavour to bring the patient into this optimum state by administration of comparatively enormous doses of disodium monohydrogen phosphate by the mouth. Our dosage amounts to 2-5 grains four times a day. Even in such large doses it is extremely difficult to maintain the desired reaction, especially at the stage of the disease when the diet tends to be more generous. The reaction is determined roughly by daily urine titrations; thus to 1 c.c. of urine add a drop of phenol red solution—a pink colour indicates a pH of 7.2 to 7.4 approximately.

Other alkalies have been tried but for one reason or another have been abandoned. For example sodium bicarbonate raises the CO<sub>2</sub> content in the tissues and CO<sub>2</sub> is a gonococcus growth stimulant. We thought there might be an appreciable danger of overalkalinization with lysis of the gonococcus in the urethra and consequent elaboration of toxic endotoxin but we believe not on clinical grounds at least that the danger is exaggerated and that a very alkaline reaction which is almost invariably temporary is of little consequence.

#### Gonococcal Exotoxin

By special cultural methods it was found by Major Diamond that when gonococci are grown on a medium rich in animal nucleo-protein approximately one third of the isolated strains develop polar bodies (Bordet's bodies), which can be demonstrated histologically by staining methods identical with those employed in the demonstration of the polar body in *Bacillus diphtheriae*. The polar bodies are composed of alpha-nucleo-protein and beta-nucleo-histone. They are only loosely attached to the bodies of the gonococci and can be separated easily from the cells by washing off the culture with 2 per cent saline solution and fractionally centrifuging the emulsion or by means of gravity the polar bodies are then found in the supernatant fluid. Since the 2 per cent saline solution dissolves the beta-nucleo-histone, the solid elements in the supernatant fluid are the alpha-nucleo-protein fraction of the polar bodies. Clinical experiments have shown that both the alpha-nucleo-protein and beta-nucleo-histone are antigenic (the beta-nucleo-histone more so than the alpha-nucleo-protein) and relatively non-toxic.

Human serum we have found to be the best vehicle for the separation of the polar bodies from the gonococci. By this means the polar bodies are retained intact and clinically the best results have been obtained by using the serum washes. However, serum has at least two serious disadvantages: an adequate supply is difficult to maintain and the question of keeping the emulsion suitable for universal use has not yet been satisfactorily accomplished although experiments are in progress to test the value of the addition of certain salts both as regards maintaining sterility and also the effect of salts on the antigenicity of the emulsion. Substitutes for serum such as Ringer's solution have been found useless for the purpose.

The employment of 2 per cent saline solution is not altogether a perfect method for the separation of the polar bodies. The beta-nucleo-histone is in solution and the alpha-nucleo-protein is in suspension but on separating the supernatant fluid from the bodies of the gonococci the fraction of the alpha-nucleo-protein is lost and it is impossible to close to the bodies of the gonococci the larger portion of them be included in the product. It has been found clinically that there is a definite provocative effect if gonococci are injected so that the use of 2 per cent saline by itself results in much less of what we call for the true gonococcal antigen—namely the polar bodies or their product.

Recently it has been found that if the pH of the 2 per cent saline during the process of separation is kept at 7.2 the alpha-nucleo-protein fraction is kept in suspension much longer and at the end of twenty-four hours the deposit of this fraction on the bodies of the gonococci is very appreciably diminished the supernatant fluid in consequence being richer in antigenic substances. This observation regarding reaction applies to the serum washes of polar bodies—they remain very appreciably longer in suspension.

For intra-urethral use the 2 per cent saline or serum washes are standardized so that the nucleo-protein of 500 000 million organisms is contained in 15 c.c.m. Larger doses than this can be given without any sign of provocation and with even better result but a polar body producing growths on nucleic acid media are never luxuriant; there is a limit to the number of culture tubes which can be dealt with in the conditions under which we work. To this 15 c.c.m. of 2 per cent saline—representing say the product of 500 000 million gonococci—is added 5 per cent sodium taurocholate and the reaction brought to a pH of 7.2.

Most samples of sodium taurocholate are acid and cause great irritation; the only preparation of sodium taurocholate which we have found to comply with our requirements is that produced by Fairbairn. To this mixture of taurocholate and polar body emulsion is added umbilical cord mucin 1 per cent up to 100 c.c.m. The dose is 20 c.c.m. intra-urethrally representing the product of 100 000 million gonococci. Formerly we had hoped that commercial mucin might be used as a substitute for the umbilical cord mucin but unfortunately all the subsequent samples we obtained were adulterated and did not represent true mucin and the results were irritative.

For intradermal subcutaneous and intramuscular administration we use the serum or 2 per cent saline emulsion of polar bodies or their product but standardized to represent 1 000 million per c.c.m.

#### In the Preparation of Exotoxin

For the preparation of endotoxin we have used strains which do not throw out the polar bodies employed in the exotoxin preparation. These strains comprise roughly 65 per cent of those isolated. They are grown for ten days on a special alkaline medium or on yeast. The culture is washed off and after being repeatedly frozen and thawed yields a product of albumens in a blue opalescent solution. It is made up to a strength representing the product of 250 million gonococci in 1 c.c.m. the diluent being chemically prepared colloidal silver. The effect of an intra-urethral injection of this preparation in a quiescent gonococcal carrier is to produce a temporary activity with the appearance of gonococci in the urethral discharge.

This product, which we believe to contain the true toxic elements of the gonococcus, is the original gonococcus product which has been employed for over four years as a "test of cure" both at Woolwich and at other military hospitals, to Major A. T. Frost, R.A.M.C., is due the credit of conceiving the possibilities of an efficient "test of cure," and of encouraging by his advice the manufacture of this product.

The provocative effect may be observed as early as twelve hours, or may be delayed several days, sometimes a week, and to cover all cases we keep the patient under observation for seven days after an endotoxin instillation before we pronounce him free from active signs. We have comparatively recently put up this "endotoxin" preparation in weaker strength—for example, 1 c.c.m., to represent 50 million of the organism—and employed it as an intra-urethral instillation much earlier in the course of the disease as a mild provocative in certain cases. This introduction of the provocative products of the gonococcus at an early stage was at the suggestion of Colonel Harrison, the idea being mildly to provoke infected urethral foci, which appeared on clinical grounds to be developing into indolent and probably latent foci.

To summarize our methods:

1. We bring the patient's urine and tissues to what we conceive to be the optimum pH reaction.

2. We attempt local immunization by the intra-urethral instillation of exotoxin (gonococcal) in mucin.

3. An effort is made to raise the general immunity response by the parenteral administration of gonococcal exotoxin vaccine.

4. Endotoxin is injected into the urethra as a "test of cure," and in certain cases to stimulate a reaction in the course of treatment.

#### *The Clinical Application*

As regards general treatment, all our patients in the army are treated in hospital, and for the first fourteen days are confined to bed on a low diet. At the end of that period they are allowed "up" and given fish diet, and graduated exercises are permitted, these latter are not special exercises, but comprise the ordinary hospital fatigues, which vary from quite light duties to comparatively heavy work.

Urethral smears are taken and examined microscopically daily, and a rough daily estimation of urine pH value is made. Immediately the case is diagnosed routine local treatment is commenced, this consists of an irrigation, followed by an intra-urethral exotoxin instillation, which the patient retains in the bladder and urethra for as long as possible—three hours or more. At the same time he receives an intradermal injection of exotoxin vaccine into the skin of the shaft of the penis, and an intramuscular injection of the same vaccine at any convenient site.

As regards the intra-urethral instillation, this is repeated as soon as the urine pH becomes optimum, and subsequently whenever urethral smears show the presence of gonococci throughout the course of the disease. This instillation causes no irritation or provocative effect, and in practice it can be repeated whenever an antigenic or ameliorative action is desired. As regards the intradermal injection, this route and site are chosen with the object of stimulating the local reticulo-endothelial system, in which immune bodies are manufactured. The administration at this site causes a slight local reaction and a definite temporary tenderness of the lymph glands of the groin. The intramuscular injection causes only the slightest local reaction.

The two initial doses by the intradermal and intramuscular routes are 0.2 c.c.m. = 200 million respectively. In the average case they are repeated at ten-day intervals, the intradermal dose remaining the same, but the intramuscular doses are gradually increased. Every case is treated on its own merits as regards intervals and dosage, many cases can be given larger doses at shorter intervals.

When, on clinical grounds, the course of events justifies the consideration of cure, the patient receives an intra-urethral injection of endotoxin, the dose being 1 c.c.m. = 250 million. This is to provoke into activity any latent active foci. If following this provocative injection the case

relapses, treatment with exotoxin intramuscularly is repeated. Should there be no recrudescence after seven days' observation the patient leaves the hospital, there have been very few subsequent relapses.

For a long time we had observed that although there might be an immediate recrudescence of the disease following an endotoxin injection as a "test of cure," the subsequent course of events was good. When this "flare up" of the disease had settled down the case went on to recovery, and subsequent endotoxin injections failed to provoke a relapse. This induced us to try the effect of endotoxin locally in its original strength at an earlier stage of the disease, but the results were not good, there was severe provocation in the average case, and these followed what appeared to be a prolonged "negative phase."

Lately we have reduced the strength of endotoxin for special use in treatment to 1 c.c.m. = 50 million, and to distinguish it from the original product used as the "test of cure" we have called it "treatment endotoxin." Thus, by reducing the dose, we can employ it much earlier in the course of the disease as a mild provocative. For example, quite a fair proportion of cases are apparently cured clinically after one or two initial instillations of exotoxin. These cases often progress until the third week without any active signs, when they relapse with a "gleet" showing gonococci occasionally. They may go on in this state indefinitely, the origin of the trouble being a few local submucous foci which have become indolent and resistant. The instillation of the "treatment endotoxin" at an earlier stage would appear to be of use as a mild provocative of such indolent foci, and this specific stimulation gives the necessary flip to complete their cure.

Although we believe that endotoxin contrasts the two toxic derivatives of gonococcal metabolism, there is no doubt that clinical experiences point to the fact that it also possesses antigenic properties when administered in correct dosage and at the right time in the course of the disease. Major A. T. Frost, R.A.M.C., observed this clinical fact in the early days when Major Leonard first produced endotoxin, but we have been inclined to forget it in our enthusiasm to produce a non-toxic exotoxin.

#### *Deductions and Results of Treatment*

Except in a general way we do not venture, at this stage, to claim that in employing these methods for the treatment of gonorrhoea we have elaborated a perfect line of treatment, or even that we have very appreciably decreased the duration of the disease. We feel that in attacking gonorrhoea by these special polar-body producing vaccines we have accidentally tackled the most difficult disease in which to apply these methods. The gonococcus is notoriously a toxic organism, and the anatomy of gonorrhoea is exceptionally difficult.

Another unfortunate fact was the elaboration of endotoxin—our "test of cure"—before the production of the non-toxic exotoxin. By applying endotoxin as our "test of cure" our standard of cure is exceedingly high—in the opinion of many, too high. Certainly patients are kept in hospital when to all intents and purposes they are clinically cured, for they are incapable of being provoked to relapse by any other method than by endotoxin. If we had not employed endotoxin we might have produced some excellent statistics as to days under treatment. However, we are conscious that there has been a general all round improvement clinically. Complications are comparatively rare, and the relapse incidence is lower than it has ever been. The most striking feature is the great diminution of the urethral discharge with corresponding decrease in the number of gonococci in the films after an intra-urethral instillation of exotoxin. In an early acute case, with all essentials at an optimum, such as the pH reaction and efficient irrigation, the sequel of events is dramatic. Naturally such happy results are not frequent, but they occur sufficiently often to convince even the sceptic that their occurrence is no mere coincidence.

All of us who have followed this research from the beginning feel that we have not yet perfected our methods of application and that we are not getting the optimum of results which we are so confident are to be obtained. As regards the exotoxic vaccine used parenterally, its anti-

gene value is high it is non-toxic and has given very good results in many severe cases of local and metastatic complications.

#### Polar Body Production in Organisms other than the Gonococcus

Although perhaps outside the question under review the following general remarks may be of interest by way of confirmation.

Polar body which we have been able to obtain in 33 per cent of all gonococcus strains—provided the necessary elements for their formation are present in the culture medium and the physical conditions required for their development are maintained—have also been found to develop in a certain percentage of strains of every organism investigated up to the present. For example, this development has been observed in strains of *B. tuberculosis* (bovine), typhlococcus streptococci pneumococci, *Neisseria bacillus B. coli, B. catarrhalis, B. crassus, B. influenzae* (Pfeiffer) *B. septus* Hoffmann's bacillus *B. zoster* etc.

In the case of the above with the solitary exception of *B. coli* a very large percentage of the strains show this development. In the case of the true *B. diphteriae* this organism as is well known, develops polar bodies on Teichner's medium and when subcultured upon nucleic protein media shows a remarkable increased production of polar bodies.

Of interest is the culture of true Kleb-Loeffler bacilli upon Dorset egg medium the primary culture invariably shows a certain number of elements containing polar bodies apparently due to the carrying over to the medium of nucleic proteins derived from the leucocytes and cells of the membrane. In the second third and fourth subculture, however, no polar bodies are developed. However if such a non-polar body culture of Kleb-Loeffler bacilli from the third or fourth Dorset medium subculture be transferred to a nucleic-protein media an immediate and enormous development of polar bodies can be observed as early as the seventh to eighth hour of culture.

As in the case of the gonococcus, if vaccines have been cultured upon media providing for detoxication during the period of subculture and if means are taken during the process of manufacture of the vaccine to prevent further development of toxin it is noteworthy that there is a complete absence of negative phase following the administration of such vaccine as compared with the marked negative phase resulting from vaccines prepared from non-polar body producing strains. For example polar body strains of *M. catarrhalis* sterilized by means of 0.5 per cent phenol cause no immediate positive phase and amelioration of symptoms in *M. catarrhalis* infections. On the other hand if such vaccines are heated at 60°C., though a favourable antigenic action is ultimately obtained, there is a definite negative phase apparently due to the liberation of some toxin by the action of heat. The same effects are seen following the employment of gonococcus vaccines both locally and parenterally.

In tuberculosis *B. tuberculosis* will probably be of value when cultured and detoxicated with the development of polar bodies. A bovine strain of tubercle bacilli with abundant polar body production brought about marked clinical improvement in a case of pulmonary hemorrhage, and with no evidence of negative phase.

Observation of the serum ferments in the mononuclear digestion of a polymorph leucocyte shows the following invariable time reactions. The ectoplasm of the cell is first digested leaving the nuclear lobes free in the ectoplasm of the mononuclear, the nuclear reticulum disappears and the lobes are stained a uniform blue. Subsequently the nuclear lobes gradually become smaller and smaller until the protoplasm is dissolved by the escape of the reticulo-endothelial cell vacuole.

Preceding similar is the course of events in the case of the polymorphonuclear leucocyte laden with polar body-containing gonococci here the ectoplasm of the polymorph cell and that of the gonococcus first disappears leaving the nuclear lobes and polar body granules free in the mononuclear ectoplasm. Subsequently these disappear at a much later period.

It is possible that in the above phenomena we have an explanation of the positive and negative phases resulting from vaccine administration—the negative phase being due to the liberation of endotoxin from the early digestion of the ectoplasm of the organism whereas the positive phase may occur later as a result of the liberation of the antigenic complexes present in the polar body fraction of the organism.

If this explanation is a true one the negative phase as a result of vaccine administration does not appear to be necessary to the development of the ameliorative positive phase—this being confirmed by the fact that it is possible with properly detoxicated polar body producing strains of all organisms to bring about immediate positive phases with clinical improvement.

This has been our experience after eighteen months' employment of this toxin-free gonococcus vaccine, provided every precaution is taken against the elaboration of endotoxin during manufacture. In a certain number of cases when, for experimental reasons various modifications in the technique of culture and preparation have resulted in the evolution of a negative phase this has invariably been found to be the result of the presence of endotoxin caused by faulty methods of manufacture.

#### DISCUSSION

Colonel HARRISON said he had always thought that these variations in potency were due to differences in the strains of gonococci employed to make the vaccine and he had also hoped that perhaps by means of special cultural methods the antigenic properties of the vaccine might be enhanced. He had had some of the new vaccine satisfactorily prepared and tested at St. Thomas's Hospital. So far as could be ascertained from investigation of only a few cases by Dr. Oliver utilizing the complement fixation test they had established that the polar body vaccine was of definite value in raising the production of antigen. Clinically they had had one brilliant result—an absolute cure in three days after one injection, notwithstanding the most rigorous efforts to excite a relapse. Other cases had cleared up more quickly than usual but had then relapsed. He asked, Why should the vaccine-producing body be called endotoxin when it was not toxic?

The PRESIDENT believed that the authors had opened up a subject which might eventually yield important results in the treatment of gonococcal infections and also produce an explanation of the discrepancies known to all who had used vaccines for gonorrhoea and other infections. There was a large field for a reliable vaccine therapy in the treatment of female gonorrhoea.

Major LANGE in reply said that the term "endotoxin" was scientifically correct as the substance was the product of the disintegration of the gonococcus. The term exotoxin was more debatable as it was doubtful whether the substance was true toxin but it was difficult to find a more appropriate and descriptive name.

## WORLD EPIDEMIC AND THEIR RELATIONSHIP AS CAUSE AND EFFECT TO SOCIAL CONDITIONS

BY

G. MATHESON, LL.M., M.D.  
Medical Officer, Scottish Board of Health

ONE who speaks with authority has told us that—

There are nine hundred ways of contracting Typhoid fever and a single one of them is right.

Much of some might be said with regard to his art, only the number of methods would require to be indefinitely extended since almost every historian has his own views of the manner in which it should be written and there is scarcely a philosopher from Aristotle onwards, who has not tried to show the professed historian how his work should be done. The reader of history therefore comes under a spell of infinite variety. In one volume he will

A paper communicated to the Section of the History of Medicine at the Annual Meeting of the British Medical Association, Edinburgh, July 1917.

find the doings and sayings of the kings minutely recorded, while his next author will write as if the various statutes were the only things worth remembrance. After that he may meet the historian whose pen will service waste a drop of ink on these things, but acts on Johnson's words

"How small of all that human hearts endure,  
That part which law or kings can cause or cure"

History, of course, has only too often been perverted to the purpose of the pure partisan or propagandist but with all this variety of point of view it is at least curious that the influence of disease on the history of a nation or people has been almost entirely overlooked. No one can deny that ill health very greatly affects the individual and may make or mar his life work, but the biographer also for the most part minimizes or misses its significance.

Not can it be said that the medical man turned biographer has been much more successful. The reason for that perhaps lies in the fact that he is not so much writing a biography as proving a thesis. In one such book, if I remember rightly, the author showed to his own satisfaction that all his subjects suffered from eyestrain or had errors of astigmatism. In another the remarkable men and women whose lives were sketched were proved to have been insane. I need only say a word in passing as to the efforts of the psycho-analysts in this direction, they have at least succeeded in adding a new turn to death.

It is true, indeed, that almost every history records such dramatic events as when

"The Angel of Death spread his wings to the blast  
And breathed in the face of the foe as he passed",

so that a siege was suddenly raised or a hostile army rapidly destroyed. But it is no less true that the remote and less obvious consequences of terrible and world-wide epidemics have failed to gain recognition. Thus Hume only devotes one short paragraph of sixteen lines to the Black Death, and seems to have been prompted to mention it merely because it interrupted the festivities held to celebrate Edward's victories on the Continent, and because it prolonged the truce entered into between him and the King of France. It is still more strange to find Green, whose ideas as to the proper subject matter of history were so different from those of Hume, failing to notice the awful aftermath of that pestilence. Fortunately the term of this neglect has now passed, and we stand in the dawn of a new day, of the brightness of which there is an excellent augury in the book of W. H. S. Jones, *Malaria and Greek History*. The reason for this welcome change is to be found in the interest recently awakened in the medical mind as to the story of medicine in bygone ages. To-day for the first time the British Medical Association has assigned a special Section at the Annual Meeting to the history of medicine, and this is in itself a testimony to the widespread interest in the subject and an acknowledgement of its importance.

The theme allotted to me is manifestly too wide to be developed adequately in the time at my disposal, even if I had the competent knowledge to do so. As it is denied to me to enter the promised land, I esteem it a privilege to have even a glimpse of it from my lowly Pisgah, and I shall be happy if I may rightly discern the lines along which others may be able to enter into possession.

Let me, then, direct attention to three dates: 430 B.C., A.D. 542, and A.D. 1348—periods when Death held such high carnival throughout the world that the survivors thought it a miracle to find themselves alive. Now if the mind be cast back to the century which followed each of these dates, it will be found to be marked by events of world-wide importance. In 430 B.C. Greece was at the height of its power, but one hundred years later it had fallen before barbarous Macedon, and Alexander had pushed his conquests from Egypt to India. In A.D. 542 Justinian at Constantinople and Chosroes in Persia were each at the head of a long established and strong empire, and yet within a century the Arabs had set out on a career of conquest that wiped the empire of Persia off the map, and deprived the Byzantine ruler of half his dominions. Then in 1353, ten years after the Black Death, a fresh race of barbarians, the Turks, first set foot in

Europe, at Gallipoli, that shrine of dolorous memory to all of British blood, and passed from victory to victory till in 1453 the Byzantine empire was numbered with the things of the past.

It may be said that these are merely curious coincidences and nothing more, that the immediately preceding circumstances brought these events about, and that the direct effects of the pestilence had worn themselves out long before. It may be so, but the matter seems well worth more careful investigation. However widespread the pestilence there must have been some inequalities in its distribution, and in general its destructive powers must have been greater in the closely packed towns than in the more widely spread population of the country. We certainly know that the popular method of trying to avoid contagion was for the citizens to fly to rural districts. Other things being equal, then, the dreadful effects of plague must have been much heavier in civilized communities than among barbarians, for the city is the symbol of civilization. For these and many other reasons I believe that there is real ground for thinking that it was pestilence that gave the Macedonian, the Arab, and the Turk the first push on the road to power and empire.

This idea is greatly strengthened if we consider in a little more detail what happened after the Black Death. We know that the cities suffered so much from the loss of citizens that various means were adopted to attract fresh inhabitants. These efforts were successful through the rapid influx of people from the country. As a result and because of the lessened power of the nobles owing to the drain of their rural retainers, the cities rose in power and influence. Thus we find that by the treaty of Stralsund in 1371 the Hansa League of towns entered upon its period of greatest prosperity.

The weakened power of the nobles led to the downfall of the feudal system, which was the ministry of the land and barons, its end was hastened by the protection given by the kings to the towns. By the gradual absorption of fiefs the power of the king waxed stronger and stronger till by the end of the fifteenth century all the land became vested in him alone, and the kings of England, France and Spain became absolute monarchs. This trend toward concentration of sovereignty had already been manifested in 1397 in the treaty of Kalmar, which brought Norway, Sweden, and Denmark under one crown.

The indiscriminate visitation by death of the estate and the hovel gave a fearful object lesson of the essential equality of man. When the corpse of the lord was dragged in the same tumbrel as that of the labourer and both were cast into the same trench, it was inevitable that the question should be asked why it should be the privilege of the one to have power and wealth, while the lot of the other should be poverty and labour. In England it found popular expression in the refrain,

"When Adam delved and Eve span,  
Who was then the gentleman?"

Besides, owing to the lack of labour, the peasant found himself to be a person of importance in the State. Land had to be tilled if the nation was to escape starvation, so that landowners competed with one another in offers of wages for labour. Parliament stepped in with ineffective laws to try and fix wages or to prevent the labourer leaving the land. And so came the insurrection of the peasants of England, which had already been preceded by a similar movement in France—the "Jacquerie." It was thus the pestilence which first enlisted the labourers against the army of capitalism.

It is to this period also that we must assign the real beginning of the middle classes. Naturally the citizens were the begetters of the prosperity of the towns, and the riches and power of the towns were reflected in the affluence and influence of the burghesses. In the order of things, the accumulation of wealth is gradual, but the great morbid brought undreamt-of riches into unaccustomed hands, which as rapidly dissipated the money in reckless prodigality. Such people thought of nothing but rich clothing, sumptuous feasts, and generally riotous living. Many social customs were changed. The cloak was cut down into a garment which only reached the knee and was still further abbreviated, and as it now closely fitted to the body it was no

longer drawn over the head but was left open in front and fastened with buttons. The indecency of the new fashion, the jacket was the theme of many homilies.

In no direction perhaps did the Black Death make greater havoc than in regard to religion. To some the mortality brought a greater sense of their own sinfulness and the need of a greater dependence on Divine providence. But even the devotions that were the consequence of this feeling were of a different character from those previously followed. Such people still kept within the line of orthodoxy, but there were many others to whom the extraordinary fatality among the priesthood brought other thoughts. To them it was a sign of God's judgment upon the wickedness of the clergy, of whom they had been a part. Thus Wacht taught that only those priests who were in a state of grace could properly administer the sacrament. So many parishes were left destitute of incumbents that the faithful became accustomed to the absence of the spiritual directors and began to fend for themselves. From this time we can trace the growth of a somewhat Presbyterian cast of thought. It is significant that the flatterers were almost all lay people and that priests or religious when present did not direct the proceeding. The efforts to make good the depleted ranks of the clergy and to fill up the vacant places in the monasteries were far from attaining success. The monks were to a great extent made up and places filled but in too many instances the hasty selection of unsuitable recruits and the inadequate training to which they were submitted gave to the lay people pastors quite unfitted to discharge their duties adequately. It is abundantly clear indeed that with the harvest of death there was a wide prevalence of the dragons' teeth which were to grow up in due time into an army of rebels against the authority of the Church of Rome. Further merely applied the torch the Black Death had already assembled the fragments.

The moral and religious effects that follow the contemplation of death on a great scale may be noted even in our own time. Four years of war on a scale unparalleled in history followed by an epidemic which perhaps can off even more than the war, may give us some faint idea of what happened during the Black Death. As this, so now the non-believers insist on the increased selfishness of mankind the blurring of religious feeling, the inordinate pursuit of pleasure, the new manner for dining the immodesty of coarseness and of garments. It is no part of my duty to inquire to what extent these complaints are justified. I merely note that the symptoms are similar and the resemblance might be greatly multiplied. It was in a time of pestilence that Max Augustin, a singer and bagpipe player of Vienna, composed his well known song. Is it a further coincidence that his tune has received a new consecration in the froth-blowers' anthem?

## Memoranda;

### MEDICAL, SURGICAL, OBSTETRICAL

#### TREATMENT OF VARICOSE VEINS BY INJECTION

THE inquiry of Major General T. M. Corker in your issue of August 6th (p. 244) leads me to send a brief report of my own experience during the last six months in the treatment of varicose veins by injection. The number of cases treated is small and too short a time has expired to allow me to judge the permanence of the results obtained. I do not wish to pronounce a final opinion at present.

Of six cases which have been completed I treated two by very large and extensive varicosities in the veins of both legs, two were early cases and two were still standing but not extensive, only one limb being affected. Sodium silicofluoride solutions in 20 and 50 per cent strengths have been used, because the same can be prepared and sterilized at home and the patients have attended at my house for treatment. The two severe cases have had many injections I have felt very little pain, and I have shown no evidence of spreading thrombosis. On the other hand relief was

felt after the first treatment. Both patients have recorded burning and stinging sensations for 10 to 15 days and they appear quite satisfied with the result.

Of the lighter cases one was cured by two treatments of seven punctures, although one patient who was extremely nervous did not like kindly to the injections and never discontinued. I should consider this as a failure. A third and much pain and after her second treatment showed signs of phlebitis extending down towards the ankle not upward. The veins are smaller, and I am hoping for a cure. The fourth had developed varicose veins in the right leg during pregnancy, the veins were getting bigger quickly, and she complained of increasing pain. Two treatments of three injections each were given with one week's interval. The pain was relieved and the veins in the leg became smaller and quite hard. About the same time I attended another lady who had developed varicose veins of the internal saphenous during pregnancy. No treatment was given, and I was interested to find a few days later delivery, that the vein had become thrombosed from the saphenous opening downward for about four inches—evidently a natural cure, by a process similar to that which follows injection.

Up to the present I have followed the instructions given by Prof. or Sierd and Dr. Morton. I have seen no sign of danger from thrombosis and no long standing of blood from escape of the injected fluid into the tissues. A fine sharp needle and a little pressure in manipulation are needed and, of course, surgical cleanliness. An expensive outfit is not required.

This method of treatment is to be recommended for the varicose veins but should not be used for patients with dilated superficial veins following phlebotomy.

#### ACUTE APPENDICITIS IN AN INFANT

INCISIONS OF THE VERIFORM APPENDIX BEING FOUND IN A HERNIAL SAC HAVE BEEN REPORTED IN THE JOURNALS FROM TIME TO TIME, BUT THE UNUSUAL HISTORY AND FEATURES OF THE FOLLOWING CASE MAKE IT WORTHY OF RECORD.

In September 1922 a male infant aged 15 weeks was admitted to the Royal Manchester Children's Hospital with the following progress: vomiting and inflammation of the right side of the abdomen more marked on the right side. The child formed a riding boot shaped inflammation measuring about 3 inches in diameter. The temperature was 102.2 and the pulse 120 (approximate).

A provisional diagnosis of acute enteritis was made and treatment of the abdomen in the form of hot fomentations. The fever subsided and the inflammation disappeared. The child was discharged home in good health having gained 14 lbs in weight during convalescence.

Two years later the same child was brought back to hospital for further treatment. A discharging sinus had formed in the scrotum shortly after the hernia had been reduced and a rupture had been present on the right side since operation and was becoming increasingly prominent and troublesome. A typical right testicular swelling could be partially but not wholly reduced and a small indurated mass was present on the art or a part of the right side of the scrotum from which a clear green fluid of discharge could be expressed.

An operation for reduction of the hernia was performed by Mr. A. H. Southam on September 1, 1925. A large hernial sac containing a large amount of intestine was found and the contents were returned to the abdomen. The hernia was then closed and the scrotum was treated with the usual after-treatment. The child was discharged home in good health and the hernia was no longer a problem.

It is interesting to note that the previous treatment had originated in a hernia of the scrotum which must be unusual at such an early age and which had resulted in the formation of a pathological appendix tumor.

I am indebted to Mr. A. H. Southam under whose care the boy came for permission to place this case on record.

### THE SYMPATHETIC SYSTEM IN MINERS' NYSTAGMUS

Many cases of miners' nystagmus pass through my hands, and I have examined the pupil with great care. Apparently there is no dilatation. This answers Dr Baldwin's question (July 30th, p 191). The chief symptoms of the disease, however, might well be due to hypertonicity of the sympathetic nervous system, and the conditions under which a miner works certainly involve overaction of this system—for example, the maintenance of unnatural posture and a fully dilated pupil.

It appears to be fairly well established that miners' nystagmus is associated with lack of light. There is considerable evidence, from work done at Jesionek's clinic at Giessen, that ultra-violet light has a definite effect on the sympathetic nerve endings. Also in Rygaard's disease good results have been obtained by treatment with ultra-violet light, and this is said to be due to indirect action through the sympathetic nerves.

It seems possible, therefore, that a considerable deprivation of retinal light during a man's employment as a miner, combined with the extra call upon the sympathetic nervous system due to unnatural posture and dilated pupil, may bring about a more or less permanent condition of sympathetic hypertonicity. Such sympathetic hypertonicity might account for all the symptoms of miners' nystagmus—tachycardia, disordered tone of the eye muscles (clonus?), sweating, psycho-neurotic changes, etc.

This suggestion is merely tentative and naturally can only be expressed in outline here, but the chain of evidence is so strong that it seems worth while to test the effect of retinal light upon patients suffering from miners' nystagmus. For some time past I have been investigating this matter, and arrangements have been made for me to test the treatment.

### COINS IN THE OESOPHAGUS

MR KENNETH LEE'S memorandum on coins in the oesophagus (April 23rd, p 761) recalls to my mind an interesting case of the same kind which came under my care when casualty house-surgeon in 1916 at St Mary's Hospital.

A boy, aged about 9 years, was brought to the casualty department with the history that he had swallowed a halfpenny a fortnight previously, and that it had not been passed by the bowel. A rectal examination at the hospital showed the halfpenny fixed at the cardiac end of the oesophagus. It was decided to attempt to recover it with a coin catcher.

The boy was anaesthetized in the x-ray room and the coin located by the x-rays. By gently insinuating the coin catcher into the oesophagus until it reached the level of the coin, I managed, with much difficulty, to grip the halfpenny with the teeth of the instrument, and pulled it up gently to the boy's mouth. The grip on the coin was now relaxed, but the boy gulped suddenly and swallowed the coin again.

The entire procedure had to be repeated for the coin had reached the same level in the gullet as when first swallowed. Before the second attempt was made it occurred to me that it might be easier to push the coin from the oesophagus into the stomach, but a second attempt finally recovered the halfpenny.

The case is worthy of record because it shows that a small coin does not always pass from the oesophagus into the bowel with ease.

## Reports of Societies.

### SPONTANEOUS RUPTURE OF THE UTERUS

At a meeting of the Edinburgh Obstetrical Society, on June 28th, with Professor JONATHAN, the President, in the chair, Professor JAMES HENDRY (Glasgow) read a paper on spontaneous rupture of the uterus before or during labour.

Professor HENDRY described four cases of spontaneous rupture which had recently come under his care in Glasgow, and referred to 54 other cases which he had extracted from the literature since January 1st, 1926. He said that it was impossible to ascribe rupture to one cause only. In 21 cases it had followed a previous Caesarean section and in two of these the lower uterine segment incision had

been used, 16 of the ruptures having occurred during pregnancy and only seven during labour. It would seem from the Statistics that induction of labour after a previous Caesarean section was liable to cause rupture. In one of Professor Hendry's cases rupture had occurred through the whole length of a previous Caesarean section scar. In 10 other cases rupture had followed some previous intrauterine manipulation such as manual removal of the placenta at a previous confinement. No case of rupture following a myomectomy was noted in the series. In one of Professor Hendry's patients rupture was associated with a deep tear of the cervix which had occurred at a previous labour. In four cases pituitary extract was regarded as a causal factor, though many French and Spanish obstetricians had reported no cases of rupture following the use of pituitary. In five cases prolonged labour due to various abnormalities was cited as the cause of rupture. In two of Professor Hendry's cases the presentation was a brow in one and an occipito-posterior in the other, which he considered etiological factors in the rupture. No patient had shown the usual classical symptoms of rupture, and in one instance there were practically no symptoms, the rupture being diagnosed by the distinct feeling of the foetus and the inability to produce any response of contraction of the uterine wall over the foetus. To this type Professor Hendry ascribed the name "silent rupture," and said that its recognition was extremely difficult. With regard to diagnosis he laid special stress on the easy palpation of the foetal parts and the inability to get the uterus to contract over them by gentle massage. Another important sign was the recession of the presenting part from its position in the pelvic brim which occurred in two of Professor Hendry's patients, the amount of blood lost either intra-abdominally or externally was always very little and did not exceed six to eight ounces. All his patients had been treated by supravaginal hysterectomy with invariably good results.

### Therapeutic Abortion

Dr H. S. Davidson read a paper on therapeutic abortion with special methods of induction, with particular reference to cases in which abortion had been induced either at the Royal Maternity Hospital, Edinburgh, or in his own private practice since 1923. The first reason for induction which he discussed was hyperemesis gravidarum, in which he thought that induction should be performed if the pulse rate was consistently over 100 for forty-eight hours. It was shown from his own results compared with those of the hospital that the earlier the induction after the forty-eight hours the better it was for the patient, there having been no mortality in any of Dr Davidson's patients. He also laid stress on the importance of jaundice as a bad prognostic sign, but he considered the state of the myocardium was much more important than the state of the liver with regard to mortality. He then discussed heart disease and phthisis in pregnancy, and stated that in some of these cases abortion had to be induced. Albuminuria, sleepiness, and mental conditions were also discussed with regard to induction of abortion. Dr Davidson divided the methods employed into the slow and the rapid. In the former dilatation and packing of the uterus with gauze either with or without destroying the ovum was considered the simplest procedure, the abortion might be expected to occur in from three to five days' time. This method was considered eminently suitable in cases where no haste was required. Induction by means of tents was a useful method when the uterus had to be cleared out within forty-eight hours at the most. Of the rapid methods vaginal hysterotomy was said to be suitable only in multiparous patients. Dr Davidson had performed abdominal hysterotomy in several cases with excellent results. The operation was easy, and the amount of shock was less than in the case of vaginal hysterotomy. It was the operation of election when sterilization had to be effected at the same time, and it would seem to be a very useful method in cases of hydatid mole, since the uterus could be cleared out under direct vision and not by touch. He concluded by asserting that the life of the mother was much more important than the life of the child, especially as it was impossible to foretell whether the child would be an asset or otherwise to the community.

## THE RESPONSES OF THE BLOOD VESSELS OF THE HUMAN SKIN

The wealth of experimental material presented in this monograph on *The Blood Vessels of the Human Skin and their Responses* had already formed the basis of Sir Thomas Lewis's Croonian Lectures, delivered before the Royal College of Physicians of London in June 1926 and when an abstract was published in this JOURNAL on July 10th of that year (1926 ii, p. 61). Much of the work has appeared in detailed form in an imposing series of original monographs published chiefly in *Heart* and in the *Journal of Physiology* from 1916 onwards. Sir Thomas Lewis, with his co-workers at the time was indeed the first among the several investigators in different countries who in the past decade have contributed to the new awakening of interest in the activity of the minute blood vessels, and in its importance for the adjustment of the circulation to the needs of the tissues. His book, embodying his Silliman Lectures on the capillary blood vessels has acquainted a wider circle with much of the work in this field. In the work under review full justice is done to the collateral evidence produced by other investigators. It is a bearing on the author's own theme, there is, indeed, a bibliography containing 275 references. The book, however, is a carefully and judiciously presented and discussion of the investigation carried out during the past few years by Sir Thomas Lewis himself and his colleagues on the reactions of the small and large of the minute, blood vessels in one tissue of one species—in the skin of man. It has, accordingly, the invaluable quality the peculiar interest and authority of a personal document. We see the problem as it originally presented itself to the author. We can follow the gradual unfolding of the story the shaping and testing of every link in the chain of evidence. As the reaction of the skin vessels to each type of stimulus comes in turn under investigation we see the separate lines converging to one inevitable conclusion. The results are of high intrinsic importance but this reasoned presentation of them is of even wider interest as a demonstration of scientific method, and, in particular, of its application to the study of reactions of the normal human body.

While apparatus of precision is used where the nature of the observation demands it—as in the measurement of small localized changes in skin temperature—many of the experiments recorded and among these some of the most important employ only the simplest technique. They could be repeated by anybody possessing a Piro-Rocci armlet, a needle a flat ruler a thermometer and—the only uncommon item in the equipment—a faculty of keen and accurate observation. A few milligrams of histamine would do serviceable. With such simple tools and with a masterly ingenuity in so combining their use as to give significant results in logical sequence, Sir Thomas Lewis weaves the close fabric of his argument. From the pattern emerges a common type of vascular reaction in the human skin to mild injuries of all kinds, mechanical (chemical or thermal—the triple response), consisting of the sharply localized capillary dilatation, the coincident wheal which succeeds it and the surrounding 'flare' which is due to arterial dilatation produced by the local axon reflex. Point by point the evidence is accumulated to show that all three constituent phases of this complex response are due to the local liberation from the injured epidermal cells of a chemical substance, identical in its action with histamine, but here referred to, with proper caution, as the "H substance." The idea that injured cells may liberate such a histamine-like substance, producing a local capillary dilatation and wheal or a general circulatory collapse according to the manner and dimensions of the

injury, is not new in itself. The novelty is the production of precise and convincing evidence for what was hitherto but a plausible suggestion. In the case of the surrounding arterial dilatation, on the other hand the conception that this, though produced by a local nervous reflex, is also due to the liberation of the "H substance," acting in this instance on the sensory nerve endings is both novel and surprising. Even more so is the conclusion that peripheral liberation of the "H substance" is responsible for the vaso-dilatation and vessel formation caused by irritation of a sensory nerve, as in the Stricker-Bühner antidromic dilatation and in herpes zoster. There is some difficulty—teleological, one may admit—in the conception that vaso-dilatation resulting from such irritation of an axon having a vasodilator as well as a sensory peripheral branch, should be due to liberation of H substance in the neighbourhood of the sensory ending, and a consequent axon reflex, rather than to direct passage of impulses down the vasodilator collateral. Sir Thomas Lewis does not indeed, exclude the latter mechanism as a possible factor, but it is the former which his evidence supports and the evidence is as cogent and as irresistible as any that he brings forward.

This triple vascular reaction to injury and the chemical stimulus responsible for it constitute the central theme of the treatise. Most of the other vascular reactions described have some relation to it. Thus the reactive hyperemia following temporary arrest of the circulation is shown to be due to the accumulation of H substance during defect of the cleansing stream of the blood. The anaphylactic reaction, studied in terms of its local expression in the skin receives an interpretation of new clearness. Hitherto there was difficulty in reconciling the two lines of evidence as to its nature. There was strong reason on the one hand for attributing it to the interaction of the sensitizing antigen and a specific antibody in the living cell. On the other hand, the obvious similarity between the details of the anaphylactic reaction in different organs and different species and the effects produced by such substances as histamine in the same organs and species, had led many to support the view that a substance having this type of action on "anaphylactin," was liberated by some fermentative or other action of antibody on antigen in the blood. The two lines of evidence when viewed in the light of Lewis's demonstration lead to a common conclusion. The immediate effect of the interaction of antigen and cell fixed antibody is like that of the injury of the protoplasm by other methods: the liberation of the H substance from the cells producing in each organ or tissue in which it is thus liberated the characteristic response of that organ or tissue to histamine.

It is impossible in the scope of a review to touch upon more than a few of the numberless points of suggestive interest to be found in the monograph but one of more general significance deserves further notice. All the world of medical science knows of the leading part which Sir Thomas Lewis played in the remarkable advance in clinical knowledge of the details of the heart's action made possible by the experimental analysis of the mechanism of the normal mammalian heart beat. Here we find him conducting an investigation equally exhaustive and original into the physiological behaviour of another part of the normal circulatory mechanism. In this study of the blood vessels of normal skin he finds that man himself provides not only a possible but for many experiments the only possible subject. He is led to generalize from this experience telling us that his chief motive in writing the book was a desire to stimulate a wider study and teaching of human physiology for knowledge relating to the healthy man forms the most manifest and abiding bond between physiology and medicine. It is obvious that the data of physiology can furnish a firm foundation for human medicine only in so far as they are valid for man himself. The case of the reaction of the skin vessels is however a special one. The human skin is peculiar in its variability and in the readiness and variety of its vascular responses while the skin is pre-eminent among the organs in its harmless accessibility for experiment. In other huge domains of its activity, however as in studies of respiratory metabolism and the effect thereon

must necessarily be somewhat cursory but in spite of its comprehensive and ambitious nature the book never loses proportion in the presentation of the subject matter, and never loses interest in its manner of treating it. It is primarily a reference book although in no sense a mere encyclopedia. It reveals the vast industry and comprehensive knowledge of its author and the translator has done it every justice.

## TWO X-RAY ATLASES

A LITTLE over two years ago the first edition of McKEEN and WHITTAKER'S *X-ray Atlas of the Normal and Unnormal Structures of the Body* appeared and now a second edition<sup>1</sup> is issued. Many additional radiographs appear in the new edition, and special attention should be called to the series which show lipiodol injections of the bronchi. These have been supplied by Dr. John Cuy who also furnishes a note on the method employed.

The book has been extended by thirty-four pages, but, except for these additions is substantially the same as when first published. No attempt seems to have been made at any definite revision and many very poor and quite inadequate radiographs have been retained. One notable omission is in the part dealing with the spine, for with one exception—a lateral view of the cervical spine—no lateral view are reproduced; this is difficult to understand, as there is no doubt that in probably most cases of disease and injury the lateral view is of more importance than the antero-posterior. A further criticism might also be made that, with ample space the authors have not seen fit to add to the descriptions accompanying each radiograph. The bold statement that this or that picture is an example of this or that condition is hardly calculated to convey much information of value to a practitioner who may not be an expert and it is obvious that it is to the general practitioner that a book of this kind appeals. We venture to think that generally speaking a greater effort should have been made to point out the nature of the x-ray changes shown. This could have been done without increasing the size of the book and would have added much to its value. However, that a second edition has been called for in so short a time shows that there has been a considerable demand for the atlas and there is no doubt that it serves a useful purpose. It is a pleasant book to handle inasmuch as it is well presented and attractive, and is printed on paper which suits the illustrations and renders good reproduction of the radiographs possible.

*Atlas de Radiographie Osseuse*,<sup>2</sup> by HARET DARIATX, and QUELST, presents a series of radiographs in a somewhat novel manner. There are two reproductions of each either side by side or opposite to one another the one in the usual style while the other is the same radiograph with the outlines artificially strengthened and marginal notes stating what is the cause of each part of the shadow. The atlas is beautifully got up and is of large size but very unfortunately in the bulk and especially the more difficult parts such as the hand etc., the radiographs are by no means up to the standard of modern x-ray technique. Except for a very short introduction and at the end a few tables dealing with the data of ossification of the bones and epiphyses there is no printed matter other than the marginal notes. The material for practical purposes is divided into two main parts, the first consisting of some sixty odd reproductions of the adult human skeleton and the second with sixty illustrations dealing with the child from the time of intrauterine life to the age of 16. A book of this kind dealing only with the normal is a useful for teaching and will be valuable for occasional reference in an x-ray department. It is a novelty inasmuch as it differs from most atlases in portraying only the normal appearances and as a knowledge of the normal is essential in reading the abnormal it is a handy method of having

at hand a series of the normal in which no individual bone can be looked up whilst the marginal notes will at once indicate the various radiographic points. Medical students and those reading for a diploma in radiology will find it of value.

## NOTES ON BOOKS

THE third edition of *Kerr's Manual of Fever* has been ably revised by Dr. CLAUDE PRINGLE, medical superintendent of the Fazakerley Hospital, Liverpool, who is to be congratulated on having brought the work up to date without modifying its essential feature. The new matter includes information about the bacteriology of measles and scarlet fever, the Dick and Schultz Charlton test, immunization against scarlet fever and the antioxin treatment of the disease and the serum prophylaxis of measles. We are pleased to see that the reviewer recommends much larger dose of antioxin than the one mentioned by Dr. Kerr and that he deprecates the routine administration of alcohol in diphtheria which was advised in previous editions of the work. We have detected a few omissions. Although reference is made to Cronin's organism there is no mention in the paragraph on the etiology of measles of Trenchard's grain producing diplococcus which is more likely to be the causal agent of the disease nor do we find any reference to Ramon's antioxin erythema infectiosum or exanthema subitum to which so much attention has been given lately in Continental and American literature. We note with regret that the historical illustrations of scarlet fever and serum rashes have been removed though they might as well have been pointed out in the review of the last edition (JOURNAL, April 22nd 1922, p. 645) have been better replaced by coloured plates or omitted altogether.

*Practical Tropical Sanitation* by Dr. MINETT and SEVER represents the second edition of a somewhat smaller work by the first named author published even years ago. It is a little difficult properly to assess the value of this book as the premises that it is for sanitarians and others in tropical countries. The others from the general character of the book must mean non-medical persons and the directions to inoculate all contacts with antiplague and F4P vaccine would not come within the province of either. There is a considerable improvement on the first issue. The number of pages has been increased by fully one third and the illustrations by 25 per cent. But several pages previously occupied by the regulation and by laws in force in British Guiana have been omitted the addition are more than the mere number of pages would indicate. We note incidentally that the picture of Dr. Balfour's strap is still deprived of its emptying approach without which the flies depicted would certainly not be induced to enter. The author's experience in China enhances the value of the present edition for the former was based almost entirely on conditions in British Guiana. The most notable addition in the present issue is the final chapter on cholera for which the assistance of Mrs. Minett who has had experience in both the West India and the Far East has undoubtedly been enlisted.

For a book he has written on therapeutics in general practice Dr. CUMPLES FLEISCHER who is a frequent member of the Académie de Médecine draws on an experience of nearly fifty years. These years have taught him that in many maladies nature is still more intelligent than the doctor. It is no surprising the more to find that he has much respect for rational medication which seems to be very popular in France and still less for the rational administration of drugs. He does not believe in heavy pain but he finds that two or three grains of morphine are correct. For confirmation of the principle that his use like he advances the doubtful argument of vaccination. The other principle is that if the immediate effect of a remedy is violent its duration is short and vice versa. Upon this principle Dr. Fleischner bases his view that the cause of disease should be treated by large doses in order to speak clearly the disease on the head while the symptoms of disease should be treated by minimal doses of drugs. Dr. Fleischner is content upon the confidence inpired by the doctor's therapeutic agent of his high value. At the same time devoted to meditation such a therapeutic agent is general in the rapidity the author describes the treatment he has found successful in disease of various tract of the body.

*Kerr's Manual of Fever* Revised by CLAUDE PRINGLE, M.D., etc. Third Edition. (Oxford Medical Publications.) London: H. K. Lewis, Ltd., 1927. (Cr. 8vo pp. xv + 350. 12 figures.) 12s. 6d. net.  
*Practical Tropical Sanitation* By E. P. MINETT, M.D. DPH, D.T.M. and H. and A. G. M. SEVER, M.A., M.D. DPH. Second Edition. London: Baillière Tindall and Cox, 1927. (Fcap. 8vo pp. viii + 125. 50 figures.) 5s. net.  
*La Pratique Thérapeutique en Clinique* Par Ch. FLEISCHER, Com. m. et Gu. r. But. technique des Praticiens. Paris: J. Maloine, 1927. (Imp. 16mo pp. 3-2. 20 fr.)

<sup>1</sup> *X-ray Atlas of the Normal and Unnormal Structures of the Body* By Dr. P. McKEEN and Dr. C. WHITTAKER, DPH, FRCS, and Charles R. Whitaker, FRCS, FRCS. Second edition revised and enlarged. Edinburgh, E. and S. Livingstone, 1927. (Demy 4to pp. xvi + 250. 42 figures, 120 plates. 30s. net.)  
<sup>2</sup> *Atlas de Radiographie Osseuse. I. Squelette humain adulte*. Par C. HARET, J. DARIATX, Jean QUELST. Avec la collaboration de H. P. Chatelier. Préface du professeur Pierre Duvul. Paris: Masson et Cie, 1927. (Po. 4to pp. 123 figures, 160 fr. sans majoration.)

The sixth issue of *L'Année médicale pratique*,<sup>10</sup> edited by Dr CAMILLE LIAN, supported by a staff of thirty-three contributors, contains in alphabetical order a concise account of the chief recent contributions to medical literature. A classified list of the principal French medical works published during the year is appended.

In *Nan of Ailemore: A Highland Tragedy*<sup>11</sup> Dr A NIVEN ROBERTSON tells in easy verse a story gripping in its dramatic situations and withal attractive in the human pathos and word pictures of the Highland glens in summer and in storm. Nan is a fine independent character in love with a stalwart country man, who, while seeking his fortune abroad, is concussed, and becomes so changed that he brings evil upon all who love him, eventually causing her death. In the background there is a fine picture of a country doctor, with his self-denying ordinance. Mixed with idealism there is realism, as shown in the account of a music hall in the purlieus of a foreign city.

"Or else to see a bloated mass of flesh  
In fitting tights, 'the fattest woman known,'  
Be ide a man diseased had in its mesh,  
'The thinnest man on earth,' all skin and bone."

At the commencement of this interesting story in four cantos the reader is warned that the persons and events described in the poem are entirely imaginary, and that no reference is made or intended to any living person.

<sup>10</sup> *L'Année médicale pratique*. Edited by Dr Camille Lian. Sixième année. Paris: René Leprieux, 1927. (Gr 8vo, pp. xx + 518. 16 figures. 21 fr.)

<sup>11</sup> *Nan of Ailemore: A Highland Tragedy*. By A Niven Robertson. London: Erskine MacDonald, Ltd. 1927. (Cr 8vo, pp. 67. 3s. 6d.)

## PREPARATIONS AND APPLIANCES

### *Ultra violet and Radiographic Apparatus*

Messrs WATSON AND SONS (43, Parker Street, Kingsway, W.C.2) announce that they can supply British made carbons for ultra violet emission which are entirely reliable and cheaper than those of foreign make. It is claimed for these carbons that it is possible to standardize the ultra violet output in such a manner as to cover all requirements. The same firm has issued a second edition of a pamphlet entitled *Radiography for the Dentist*. After pointing out the possibilities of dental radiography the question of cost is discussed, and it is stated that a complete apparatus required for this form of x-ray work can really be purchased for a comparatively small sum, and that the upkeep and running expenses are moderate. The necessary apparatus is described and illustrated, and there are notes on the technique.

## MEDICAL EDUCATION IN INDIA

### REPORT BY SIR NORMAN WALKER

DURING the early part of the present year Sir Norman Walker visited the medical colleges and associated hospitals of several Indian universities, and in a report to the Secretary of State for India, which is printed in the minutes of the Executive Committee of the General Medical Council, he summarizes his observations.

Until quite recently medical education in India was directed and controlled by the Indian Medical Service. "That it is as good as it is," says Sir Norman Walker, "and in many respects it is excellent, is almost entirely due to the zeal, energy, and versatility of that Service." With the Indian Medical Service the various colleges grew up in close relationship, all the professors were presidency medical officers, and at first and for many years all of them were Europeans. So long as the Government was solely responsible for staffing the colleges almost all the candidates were holders of British qualifications, inasmuch as entrance to the Indian Medical Service, from which the staffs were drawn, could be gained only by passing an examination in London. But medical administration, including provision for medical education, has now become a provincial subject in India, and the change has been followed in the colleges everywhere by a great diminution in the number of European teachers. Methods of providing teachers other than through the Indian Medical Service have been called for, and men whose teaching experience has been small and

whose training as teachers has been brief have been appointed to professorships. Sir Norman Walker thinks it would be well if young men of promise, after a couple of years' service in a scientific department of an Indian university, were sent abroad to carry their studies further under different conditions before being appointed to chairs.

With regard to examinations, he points out that there is no pre-registration examination in India, and also that all the limitations for the matriculation examination have been removed, so that not a few candidates pass at the age of fourteen, and after two years spent in studying for the intermediate arts or science examination, find it possible to commence the study of medicine proper at 16, which is one year earlier than in this country. The level of secondary education in India is admittedly lower than in Great Britain, and no British university accepts the matriculation examination of an Indian university as equivalent to its own. After pointing out that it is easier to work hard for nine months out of twelve in Great Britain than in India, Sir Norman Walker suggests, as to the medical curriculum proper, that it would be well if all the Indian universities followed the lead of Calcutta in establishing a curriculum of six years (eighteen terms) and continued in the curriculum the study of chemistry, physics, and biology as applied to medicine.

At present the length of the medical curriculum varies in different universities from thirteen to eighteen terms. In anatomy, physiology, pathology, and materia medica and pharmacology India shows to great advantage, and the laboratories are generally satisfactory in building and equipment. Hygiene is taught usually by the officers of the public health department in the respective provinces, and the teachers are well qualified and experienced. Forensic medicine—a very important subject in India—is taught by lecturers, usually the civil surgeon or his assistant, or by the police surgeon in addition to his ordinary work. The teaching in systematic medicine, surgery, and midwifery is along lines similar to those followed by medical schools in this country twenty years ago. In practical midwifery there has been an improvement during the last few years. Madras has an excellent maternity hospital, and in Bombay the new Wadia hospital will provide opportunities for teaching second to none. The teaching of midwifery and gynecology in the Calcutta Medical College is at a high level, and in Lahore an excellent modern maternity hospital is well on the way to completion, but in Lucknow things are not so far advanced.

So far as hospitals in general are concerned, Sir Norman Walker says that some of the new ones are really excellent, and India is to be congratulated on its hospital architecture. The ophthalmic department is nearly always a special feature of Indian hospitals. In Madras the ophthalmic hospital, thanks to the zeal and perseverance of Colonel R. H. Elliot and his successors, is one of the finest in the world. The special departments for diseases of children, ear and throat, skin, venereal diseases and tuberculosis, have a long way to go to catch up with ophthalmology. The arrangements for the teaching of mental diseases also leave much to be desired. There are many large asylums in India, but they are rarely in close proximity to the medical colleges. With regard to research, Calcutta has one of the foremost schools of tropical medicine in the world, and institutes at Kasauli, Bombay, and Madras are all doing admirable work, but it is greatly to be desired that research should be active in many centres, notably the universities.

On the general subject of organization of medical education Sir Norman Walker states that what India lacks is a co-ordinating authority between the universities. That universities should be independent and should follow the lines which seem to them most fruitful is generally admitted by educationists, but when medicine is concerned the public interest is involved to a greater degree than with any of the other faculties. Here independence and autonomy must be combined with a minimum standard maintained for the public benefit. Some more satisfactory basis than periodic visitation and inspection through the direct agency of the General Medical Council should be found. The number of medical colleges has doubled since

Sir Norman Waller's first visit of inspection to India in 1922, and the need for setting up there some co-ordinating authority comparable to the General Medical Council, with which the Council could communicate, grows more urgent. The absence of any such directing authority in India is really the chief obstacle to a satisfactory solution of the problem. Pending the setting up of such a body, he suggests that a commissioner of medical qualifications and standards with a permanent office at Delhi should continue and extend the work already done by the Council's inspector, Colonel R. A. Needham, who has just completed the last of a series of visits and reports extending over a period of five years, and is now home on long leave. The General Medical Council would willingly accept the suggestion commissioner as their visitor, until a central authority can be established, and his regular reports would be of much assistance in determining whether or not recognition should be accorded or continued.

## CINEMATOGRAPHY APPLIED TO THE STUDY OF TISSUE GROWTH

DEMONSTRATION BY DR R. C. CANTI

MUCH interest was aroused at the Annual Meeting of the British Medical Association at Edinburgh by Dr R. C. Canti's cinematograph demonstration of the growth of normal and malignant tissue cells. The application of cinematography to medical research represents an advance on the study of living cells by dark ground illumination, to which we have referred more than once during the last twelve months, in this work Dr Canti was associated with the late Dr T. S. P. Strangeways, and a description of the procedure they devised was given in our issue of July 24th, 1926 (p. 155). Those interested in the subject may be referred to an article by these two authors in the *Quarterly Journal of Microscopical Science*, May, 1927, which contains some particularly good illustrations. Their research formed part of a larger investigation into the nature of cancer in progress at the Strangeways Research Hospital, Cambridge, and at St Bartholomew's Hospital.

The obvious impossibility of continuing observation over long periods of time and of retaining in the memory the ever-changing condition of the cells led to the introduction of the cinematograph. By this means a series of pictures taken at frequent and close intervals over as long a period as might be necessary, provided a record which could be referred to as often as desired. Moreover by running the film backwards, events could be observed in the reverse order of time, and thus be traced to their origin—an ideal method of conducting biological research. The tissues photographed specially for display at Edinburgh were the periosteum of the chick embryo and a malignant tumour of the rat, known as Jensen's rat sarcoma, these were cultivated at the laboratories in Cambridge. Ordinarily in cinematograph films the individual pictures are taken at the rate of 16 a second and are projected at the same speed. In the "slow motion" films the speed of taking is increased to 50 or 500 a second, or in some cases even to 5,000 a second, the projection being at the normal rate of 16 a second. The films exhibited at Edinburgh were the reverse of this, and might be termed "quick motion", the exposures were made at intervals of 3, 10, 30, or 60 seconds, and the results being projected at the speed of 16 a second gave the impression of speeding up of 50, 160, 480, or 960 times respectively. Dr Canti explained that the apparatus used had to be specially constructed. The optical parts were built on a concrete bed supported on alternate layers of concrete and sorbo sponge to prevent vibrations. The mechanical part of the apparatus was capable of running automatically for as long a period as required.

Dr Canti's first cinematograph picture showed the micro-culture slide on which the culture was prepared, the minute individual implant of tissue being just visible in the centre. The second picture, which was one of the most impressive, was taken under low magnification, and showed the whole of the original implant during incubation at 38°C for twenty-four hours. Soon after the commencement of in-

cubation the wandering cells could be seen coming out from the implant. These were quickly followed by fibroblasts growing out radially and giving the implant a fluffy appearance. This migrating continued until the field was covered, the actively amoeboid wandering cells always keeping in advance of the fibroblasts. The speeding up of this picture was 960 times, and Dr Canti explained that the audience, while being careful to realise this fact, might for the moment ignore it, as after all time was relatively unimportant. They had the advantage at this demonstration, in half an hour or so, of seeing the events which took more than five days to happen. A series of individual cells was then shown under a higher magnification undergoing cell division. The elongated fibroblast was seen to become shortened and to round up into a spherical form and, the nucleus having disappeared, the chromosomes could be seen arranged equatorially. Then followed a quick series of events. The chromosomes migrated rapidly, half to either pole of the cell, the cell developed a waist and divided, each portion underwent violent bubbling, processes of protoplasm being thrown out and withdrawn with great activity. As this gradually simmered down the two halves slowly reformed into two vegetative daughter cells and wandered away from each other, the fresh nucleus in the meanwhile gradually reappearing. Then followed a series of pictures illustrating the growth of sarcoma tissue, the cells of which were in striking contrast to the normal tissues already shown. Two varieties of cell at least were present. One, which was highly mobile, was furnished with long, actively moving pseudopodia, which ended in fine fibrillated extremities, the other, or fibroblastic type, was less mobile, in shape rounder and with undulating edges. The degeneration of some of these cells was watched, the active and more healthy cells were seen to be attracted and to adhere to the edges of those which were degenerate.

Dr Canti explained how the method of observation could be applied to the investigation of a variety of problems in many fields and in several pathological, pharmacological, and physiological, as well as biological research. His present line of investigation was the effect of radium irradiation on normal and malignant tissues, and the second reel dealt with his photographs to date. The radium used was in the form of radium emanation (radon), and was supplied by Professor Purvis. The quantity varied in different experiments from 70 to 150 millieuries, and the distance of the radon from the culture ranged from 4 to 7 mm. The radon was unfiltered except by the walls of the capillary glass container and the cover-slip of the tissue culture preparation. The cells were therefore receiving both beta and gamma radiation of relatively high intensity. In order to record the time at which events took place a small clock was photographed in the corner of the film. The details of the experiment and the time at which the radon was applied to the culture were noted in a caption preceding each section of the film. First the effect on normal periosteum was observed. Cell division, which was plentiful before the radon was applied, ceased immediately the spreading edge of the fibroblasts advanced no further and the movements of the cells themselves were arrested. A proportion of the fibroblasts became rounded and degenerated giving rise to the "breaking down" cells characteristic of irradiated cultures. The majority of fibroblasts however were not affected in this way. The wandering cells continued their amoeboid movements for twenty minutes after irradiation was commenced and then became still and eventually broke down. The last series of films depicted the effect of radon on the sarcoma tissues which was dramatic. Within fifteen minutes or the application of the radon the seething mass of cells was completely immobilized, and those which were in the act of cell division did not continue the process. As time went on the cells became rounded their edges became indistinct and irregular and the final stage of disintegration set in.

Sir ROBERT PHILIP, at the first demonstration, expressing the appreciation of the audience to Dr Canti for giving this demonstration three times congratulated him on his important revelation of cell life and hoped that valuable developments might follow in the near future.

## NoVA et VETERA.

### PROVINCIAL CONSULTANTS IN THE SEVENTEENTH AND EIGHTEENTH CENTURIES.

AMONG the many alterations in the social life of this country which followed on the introduction and spread of the railway system, one of the most striking was the decay of the importance of country towns. Perhaps the smaller towns, especially those within comparatively easy reach of London, suffered most.

In the novels of the end of the eighteenth century—such, for instance, as Jane Austen's *Emma*—we read of dances held in inn rooms, as in the little town of Highbury, which, if not identifiable with Epsom, was at least no further from London, and in such a small place as Uckfield in Sussex there was till recently a large assembly room in the principal inn. If such provision for social gaieties was common in minor towns, it was still more usual and greater in the large provincial capitals such as Salisbury or Exeter. At the same time the well-to-do inhabitants of such places and of the country around them often had recourse to consulting physicians and surgeons in those capitals rather than to those of the metropolis. Even later George Eliot, in her description of society in Middlemarch, writes of a physician as practising there as well as the surgeons and apothecaries. Erasmus Darwin of Lichfield is a much earlier instance, and there were, of course, many others after his time, including Sir Charles Hastings, the founder of the British Medical Association, who established himself in Worcester the year after Jane Austen's death. Worcester was indeed a good example of a county town self-contained so far as the practice of medicine went, and so continued down to our own times, as did many other cathedral towns.

In a recent correspondence in the *Times Literary Supplement*, Mr. Paul de Cistio has drawn attention to a once well known Salisbury surgeon, Mr. Edward Goldwyer or Goldwire, who died in 1774. His father, William, had also practised in Salisbury, and two of his brothers were practitioners in Blandford and Marlborough respectively. Mr. de Cistio argues with much force that Edward Goldwyer was probably the surgeon who treated the first wife of Henry Fielding the novelist, when her nose was severely injured in a carriage accident, an event which made an incident in his novel *Amelia*.

That Edward Goldwyer was a surgeon of note is evident from the following letter which was found among his papers. It is given in an anonymous work in three volumes, published in 1825 under the title *Professional Anecdotes or Lull of Medical Literature*.

"Fisherton Anger Grol, October 31d 1736 Sir.—Being informed that you are the only surgeon in the city or county, that antonnes men and I being under the present unhappy circumstances, and in a very mean condition would gladly live as long as I can but by all appearances I am to be executed next March, having no friends on earth that will speak a word to save my life, nor send me a morsel of bread to keep life and soul together until that fatal day so if you will vouchsafe to come hither I will gladly sell you my body (being whole and sound) to be ordered at your discretion knowing that it will rise again at the general resurrection as well from your house as from the grave. Your answer Sir will highly oblige Yours, etc, James Brooke."

This letter was addressed "to Mr. Edward Goldwyer [sic] at his house on the Close of Salisbury." For what offence James Brooke was doomed to die we cannot tell, but it was quite probably a comparatively trivial one, such as a small theft. One would like to think that Goldwyer was able to save him from starvation and the gallows without accepting the offer of his cadaver. Such offers were prob-

ably rare, though it is said that the bereaved relatives sometimes solved themselves with the proceeds of the sale of the corpse of the lamented one. It will be remembered that her detractors alleged against Mrs. Sarah Gump that when her husband died—

"and I see him lying in Guy's Hospital with a penny piece on each eye and his wooden leg under his left arm" if certain whispers current in Kingsgate Street circles had any truth in them, she had indeed borne up surprisingly and had exerted such uncommon fortitude, as to dispose of Mr. Gump's remains for the benefit of science" (*Martin Chuzzlewit*, ch. xxix).

Goldwyer seems to have been an active pioneer in the practice of inoculation for small-pox, if Dr. Junn's reference to the fifty-three cases inoculated in Salisbury by "Mr. Goldwyre, Surgeon," applies to him.

There is a monument to an earlier medical celebrity near the west door of Salisbury Cathedral. It commemorates Dr. Drubney Turberville, who had a great reputation as an eye-surgeon and died in 1696. Dr. Walter Pope, F.R.S., who succeeded Sir Christopher Wren as professor of astronomy in Gresham College, and who himself held the degree of M.D. Oxon., composed the epitaph on Turberville, whose patient he had been. In the life of Bishop Seth Ward in Cassan's *lives of the Bishops of Salisbury* (Pt. III, p. 103), Dr. Pope gives us a lively account of Turberville and of his ways. Lilo Pope he was M.D. Oxon. It is said that it was by his mother's advice that he devoted his attention to diseases of the eyes, as "he would find it turn to a good account." The event proved her prescience, for he had crowds of patients whom he began seeing at eight o'clock every morning. "He generally prescribed to all shaving their heads and taking tobacco" (snuff?) "which he had often known do much good and never any harm to the eyes." Ophthalmology scarcely existed at that time, and the methods of regular and irregular practitioners were alike largely empirical. Here is a specimen of Turberville's methods, as recorded by his admirer Pope. The patient's eye was "protuberant and could not be contained within the lids, and seemed like a piece of raw flesh, the doctor placed him in a chair, and with a pair of scissors cut large gobbets, the blood trickling down his cheeks in abundance, and yet he seemed no more concerned than if it had been a barber cutting his hair, I was surprised at his behaviour and said to one of the bystanders, 'without doubt this is a married man, otherwise 'twere impossible to be so patient.'" (Pope was a bachelor.) What the result was of this heroic method of treating conjunctivitis we are not told.

Turberville's reputation in Salisbury spread to London, so that he was called in by the Duchess of York, to treat her daughter, afterwards Queen Anne, then a child. Other physicians and surgeons were dismissed and Turberville was put in sole charge and cured her "in a few months." It may have been during this visit to London that he was consulted by Samuel Pepys, for under the date June 22nd, 1668, we read in the Diary "Mr. Boyle refers me to one Turberville of Salisbury, lately come to town, which I will go to", and on June 25th, "then to Westminster to Dr. Turberville about my eyes, whom I met with and he did discourse, I thought leaguely about them, and takes time before he did prescribe me any thing, to think of it." Lastly, on June 29th he wrote "I stop at Dr. Turberville's and there did receive a direction for some physic, and also a glass of something to drop into my eyes, who gives me hope that I may do well." If, as Sir D'Avenant has shown is probable, Pepys's troubles were due to hypermetropia and astigmatism, no amount of drops or plasters could have cured him, although the secondary conjunctivitis might have been relieved for the time. After his death in 1696 at the advanced age of 85 Drubney Turberville's sister Mary was practising in London "with good reputation and success." No doubt she possessed his prescription books.

In recent years the pendulum of practice has begun to swing back again, for with the foundation of provincial universities and their medical schools, and the growth of hospitals in many other large towns, first-rate advice may be had without coming to London.

SATURDAY, AUGUST 20TH, 1927

## THE NATIONAL INSURANCE DRUG FUND

It should be within the recollection of all those interested that Section 2 of the Economy (Miscellaneous Provisions) Act, 1926, provides that the whole cost of medical benefit shall be a first statutory charge upon the Insurance Fund, as from January 1927 up to a maximum, including administration of 13s for each insured person entitled to that benefit. In our comments on the Economy Bill while it was passing through the House of Commons (JOURNAL, April 10th, 1926 p. 663, and April 24th, 1926, p. 750) it was explained that the Medical Benefit Fund bears the cost not only of the practitioners' capitation charges and mileage, but also of the supply of drugs and appliances to insured persons, and part of the cost of medical referees and some other administration expenses. We pointed out that it was only 'the most elementary common sense' to make these costs a primary charge on the fund as medical benefit is the fundamental provision on which all other insurance benefits depend but we expressed very emphatically the opinion that it was far from wise to limit the charge to the maximum amount prescribed, or, indeed, to fix by statute any such maximum at all. We said at that time: 'It may be doubted whether the maximum amount is really sufficient. The present capitation fee for practitioners is undoubtedly too low. The amount of work has demonstrably increased, even since the Court of Inquiry awarded the 9s. The call on the Drug Fund has increased considerably of late years, and does not yet appear to have reached its limit. On present figures alone the margin available appears to be very small, and whether by reason of an expanding call for drugs and appliances, or by reason of a justly augmented payment to medical practitioners, no one can desire a repetition of the legislative situation which arose two years ago. These fears were, we understand, shared by the Ministry of Health but our warning was unheeded by the Government, and already, in the first year of working one of the contingencies we mentioned has arisen and the situation we indicated has come about. The demands on the Drug Fund have continued to expand, and there is not enough money within the 13s limit to meet them without a radical modification of the arrangements with the pharmacists.'

A circular now issued by the Ministry of Health to Insurance Committees informs them that such a modification has been negotiated, and indicates its main features. The arrangement is that the chemists in England and Wales shall collectively accept liability for the provision of all the drugs and appliances prescribed for insured persons by insurance practitioners and that in return they shall receive collectively the maximum amount available for the purpose. The agreement is to run for six years from January 1st 1927 subject to the right of the pharmacists to ask for a revision in certain contingencies, and the Minister of Health has undertaken that during its currency the annual sum available shall not be less than 2s 9½d for each insured person concerned. There is a curious provision whereby an Insurance Committee may be able to reserve a pro-

portion (not exceeding one tenth) of its Chemists' Fund for any year for payment for those chemists who have been continuously on its list for a specified period of time. The implications of this are not fully evident but it may be interesting to watch its practical working. In addition, the Minister has undertaken to adopt every practical means with a view to checking unnecessary prescribing.

Any agreement of this general nature, though probably inevitable in the circumstances of existing legislation and the unwillingness of the Treasury to go beyond it is not very desirable in the interests of the public nor, we should have thought, in the interests of the pharmacists. It has features analogous to the former objectionable 'floating sixpence' arrangement which insurance practitioners hastened to get rid of, with all its consequential regulations at the earliest convenient moment. It gives an opportunity for adverse critics to allege that it is to the financial advantage of pharmacists in general that the quantity and quality of drugs and appliances supplied to insured persons shall be as small or as inferior as possible, and that there may be a temptation for the Ministry to bring undue pressure to bear upon insurance practitioners to restrain the amount and nature of their prescribing. Experience shows that even a consciousness of virtue is not a sufficient answer to such criticisms.

Insurance practitioners are tenacious of their right to prescribe whatever they believe to be of advantage to their insured patients. Under the present arrangements they have no financial interest whatever either in underprescribing or in overprescribing and their liberty, short of sheer extravagance, is secure. The Medical Benefit Regulations have always contained provisions under which individual cases of extravagant prescribing, whether wanton or ignorant, can be investigated and checked. Formerly, when the initiative lay with Panel Committees such action was taken from time to time. In recent years these provisions have been in abeyance at first on account of a general inquiry undertaken by the Ministry, and latterly by reason of a surprising inactivity on the part of the Ministry and its officers, to whom the initiative has now passed. The Insurance Acts Committee intervening at a late stage of the negotiations between the Ministry and the pharmacists has had to resist the suggestion that these provisions should be strengthened in the direction of allowing pharmacists more direct power to make complaints against practitioners. The existing regulations and system of pricing are to remain unchanged, and Panel Committees should, of course, do their best to facilitate any reasonable action taken in accordance therewith.

The great and continuous increase in the calls upon the Drug Fund is disquieting and practitioners as other taxpayers, are concerned to check it in so far as it involves any demand for what is more than proper and sufficient. The inquiry of the Ministry of Health already referred to disclosed the most extraordinary differences between practices and areas apparently comparable in respect to the cost of drugs and appliances per insured person. These differences have not as yet been explained and they may prove inexplicable. There are however certain considerations which may go far to account for the general, though surprisingly great increase of cost. In the first place, there is no doubt, a much greater appreciation by insured persons of their opportunity for obtaining medical advice and attention and an almost entire abandonment of their initial reluctance to take advantage of such opportunity. In the next place, there is

we believe a reaction on the part of the medical profession from that scepticism is to the value of drugs which prevailed some years ago. With this has come a more prudent and rational use of forms of medication, more expensive than the old, by reason either of their origin or of their more careful preparation and testing. Further there can be little doubt that, whereas in the early days of national health insurance most insurance practitioners thought it their duty to make themselves familiar with the official drug tariff, more recently little attention has been paid to this, and most practitioners are now almost wholly unacquainted with its peculiarities. Such want of knowledge is not blameworthy on scientific grounds, but on economic grounds it is unfortunate. This last circumstance, at any rate, is remediable, and combined action on the part of Insurance Committees and Panel Committees—such as that, for instance, which has recently been taken in Smethwick by the issue to practitioners of an admirable memorandum on the subject—is to be commended and encouraged. A revision of some of the anomalies of the tariff itself, and, more remotely, some regard for economic considerations in the official inclusion of preparations in the *British Pharmacopoeia*, would also be of service.

It is unfortunate that somewhat hurried action should have had to be taken by the Ministry of Health to meet an emergency in this matter. It is still more unfortunate that the resulting agreement should have been fixed for six years. We can only hope that all concerned will combine to reduce its manifest disadvantages.

### PROHIBITION THROUGH THE AGES

DR L. LEWIN of Berlin, who is justly famous for his knowledge of the history of drugs and poisons, published some time ago a treatise on habit-forming drugs, to which he gave the rather whimsical title *Phantastica*.<sup>1</sup> He has now published a second edition which contains his latest views. The subject is rather bewildering both in extent and variety, but the chief impression produced by the perusal of his essay is one of astonishment at the ingenuity displayed by man in all ages, and at every stage of civilization, in finding drugs to stupefy and confuse their brains. We are led through all sorts of strange passages of history, and into all the out-of-the-way corners of the earth. The fly agaric is suggested as the cause of the berserk rage of the Vikings, and atropine as the probable source of those delusions that brought so many witches to the stake. In the chapter on alcohol the author relates a few instances which he thinks prove the profound effect the drunkenness of monarchs has had on the course of history. Dr Lewin discusses all the ordinary drugs of addiction used by Europeans and gives details of others less well known. We have a short history of each drug, an account of its sources, of the action it produces on the individual, and of its sociological influence.

The spread of drug habits and the fate of the measures designed to abolish them make an interesting story which it must be confessed provides little comfort for would-be reformers since it is a record of unbroken failure. The prohibition of alcohol has been acclaimed as one of the great social experiments of the twentieth century, and it is interesting to learn that Charlemagne issued drastic edicts, but they were ineffective. Some of the ancient laws did not fail for lack of vigour. For example in 1378 the Emir Boudoun Sherboung determined to stop the consump-

tion of Indian hemp, and ordained that all hemp plants should be destroyed, and that all habitues should be imprisoned and have their teeth torn out. Indeed, the history of every common habit-forming drug is crowded with the recital of strongly worded interdictions that periodically have been launched against its use.

In the case of alcohol Lewin concludes that "not one of the penalties and prohibitions enacted since earliest times against drinking and drunkenness has had even a general, half perceptible, success." On the other hand, he relates many instances of the queer results that have followed attempts to interfere by legislation with the habits of a people. For example, the Presbyterian missions in Polynesia instituted a campaign against kava drinking, it was successful, but the natives took to alcohol instead—a far more serious scourge. It is perhaps unnecessary to add that Lewin is not optimistic regarding the success of prohibition in the United States, since he regards it as an experiment that has been tried and failed times without number.

Although he believes that it is impossible to abolish a deep-rooted custom or habit by repressive legislation, however draconic, Lewin recognizes that there is a possibility of anchoring the spread of such drug habits as morphinism and cocaine, which affect only a portion of the community, and depend upon a supply of drugs that could be abolished, or at least greatly restricted, by international agreement. He thinks that commercial interests have frustrated the efforts made in this direction at Geneva, he recalls Napoleon's saying *Le commerce n'a pas de patrie*, and adds that much worse things could be said of trade, were its activities in regard to habit-forming drugs to be correctly and frankly described.

The essay is of great interest and value, because it gives a clear general picture of the drug habits with which mankind has afflicted itself. In particular its study is to be recommended to those who propose to modify these habits by legislation.

**THE SPECIFICITY OF SCARLET FEVER STREPTOCOCCI.** There were at one time good grounds for believing that the streptococci isolated from the throats of scarlet fever patients formed a homogeneous group distinguished by their serological and then toxicogenic properties. It was hoped that by laboratory tests alone it would be possible to identify the origin of a given strain of streptococcus, and to ascertain what etiological relation it bore to the disease with which it was associated. Recent work, however, seems to render it more and more probable that the problem set by the streptococci is not to be solved so easily, these organisms are subject to considerable variation, and any attempt at rigid classification is likely to fail. Further evidence of this contention is afforded by a paper by Dr D. G. S. McLachlan in the *Journal of Hygiene* (March 26th, 1927). Studying ninety-eight strains of hemolytic streptococci isolated from scarlet fever cases, he found that all but three produced a toxic principle capable of evoking a cutaneous reaction in susceptible persons in a dilution of 1 in 1,000, the three exceptions produced a reaction only when lower dilutions were employed—1 in 100 or 1 in 250. But, on the other hand, no fewer than five out of thirty-two strains isolated from non-scarlatinal sources produced a similar toxin active at 1 in 1,000, while six others out of the same series produced a toxin active at 1 in 100 to 1 in 250. These results appear to indicate that no hard and fast line can be drawn by means of estimations of toxigenicity between streptococci of scarlatinal and of non-scarlatinal origin. Nor do neutralization tests with immune sera

afford much help. Of nine or eight scarlatinal toxins tested, eight or eight were neutralized by a specific anti-toxin serum or two or two non-scarlatinal toxins tested, eleven were neutralized by the same serum. Though the scarlatinal toxins appeared to differ among themselves there was no indication that their neutralization by a specific serum differed in any way from that of the non-scarlatinal toxins. The author considers that these tests show that the scarlatinal streptococci are closely related to other haemolytic streptococci, and illustrate the difficulty of demonstrating satisfactorily that *Streptococcus scarlatinae* is a distinct variety characterized by specific toxigenic properties. Undoubtedly it would be easier to study this problem if only there were a suitable laboratory animal that reacted to cutaneous injections of streptococcal toxin. So far, with the exception of certain experiments on young goats, all tests of toxicity have had to be conducted on human volunteers. Various investigators, however, have stated that by artificial immunization laboratory animals can be sensitized to the toxin. Professor T. J. Mackie and Dr. D. G. S. McLachlan<sup>1</sup> were able by repeated injections of living organisms, to produce cutaneous sensitiveness in guinea pigs to scarlatinal toxins. But further investigations showed that the reaction occurred only when high concentrations of toxin were used, that the reaction was generally mild, that the active principle in the filtrate was not inactivated completely even after three and a half hours' exposure to a temperature of 100° C., and that the sensitive strain was not specific. They conclude that the skin reaction in sensitized guinea pigs is not definitely comparable with the Dick reaction in persons susceptible to scarlet fever.

#### VISCERAL MANIFESTATIONS OF TERTIARY SYPHILIS

It is interesting to note the swing of the pendulum of medical opinion on visceral manifestations of tertiary syphilis. In a note published on Mar 7th (p. 835) Mr. Rodney Malingot, in recording a case of gummatous colitis, called attention to the change of attitude in the medical profession towards syphilis of the large intestine. The syphilitic, he said, used to be regarded as one of the commonest forms of intestinal stricture; opinion has now swung round almost entirely to the opposite view. In a recent communication to *l'Académie de Médecine* (March 1st) Drs. Emile Sergent and R. Benda mention the obit on from which Dr. Letulle has recently drawn pulmonary syphilis and with this introduction describe their observations on tertiary syphilis in the lesser bronchial tubes. They are convinced that some of their cases showed bronchial sclerosis solely due to syphilis, while others were possibly open to two interpretations that they were due to tuberculous disease in syphilitic subjects. In the first group there were eight cases in which syphilis was evident and tuberculosis could be ruled out thorough examination was made for traces of other diseases but the only case of doubt in the group was a man who had been gassed in the war. In the eight cases of the second group, although syphilis was present and the bacillus of Koch could not be found the occurrence of haemoptysis, and the discovery of nodular formation on x-ray examination prevented the exclusion of tuberculosis. In confirmation of the views the authors call attention to the recognized predilection of syphilis for the large bronchi, the frequency of the origin of dilatation of the bronchi from syphilis, and the predominance of lesions in the bronchioles in pulmonary syphilis. Drs. Sergent and Benda speak of syphilitic sclerosis of all the viscera as being generally admitted, they also regard it as uncontested that syphilitic antecedents are frequent in the subjects of tuberculous fibrosis. They conclude that in any discussion of syphilis of the respiratory tract consideration should be given to

disease of the middle and smaller bronchi, and that this form of the disorder should be distinguished from syphilitic bronchiectasis. As the affection is not fatal, autopsies in chronic syphilitic bronchitis are rare, but the authors express the hope that the condition will be sought for during *post mortem* examination of old specific cases, such as those with manifestations of tabes or arthritis.

#### NATIONAL HEALTH INSURANCE AMENDMENTS

Two months ago we drew attention (*JOURNAL* June 18th, p. 1116) to the fact that the Government was considering the introduction, either in the autumn session this year or early next year, of a bill to amend the National Health Insurance Acts in some important particulars. During the past week it has been stated apparently with authority, that this bill is now drafted, and that the proposals have been considered by the Ministry's Consultative Council of Approved Societies. Presumably, if the Ministry's Medical Consultative Council had been functioning, the proposals might have been submitted for its observations also. This, however, being obsolete, apparently with the acquiescence of all concerned, there are strong reasons why the proposals should be placed before the Insurance Acts Committee and Council of the British Medical Association. It is true, as stated in our previous note, that the approved societies insist on restricting the amendments of the Ministry to a relatively small field. However much the Ministry may wish to carry out the simpler, more urgent, and more beneficial of the recommendations of the Royal Commission, it is not to be allowed to do so. The Royal Commission, it will be remembered, unanimously recommended that an extension of medical benefit to include consultant and specialist services with laboratory provision was urgent, was "immediately possible," and would probably cost not more than a million and a half per annum, and that an extension to make dental benefit a statutory instead of an additional benefit was placed much further down on the list of desirable extensions. The possibility of carrying this recommendation into effect lies either in the Ministry and the Government insisting on it by legislation, or in the approved societies consenting thereto. It is understood that the societies have refused their consent, and it may be held by some that they are placing the conservation of their individual power and financial strength above the common interests of the insured population. However restricted, in these circumstances, the amending proposals of the Government may be, it is still possible that they may include suggestions some of which will require the co-operation of the medical profession, and certain that they must include proposals which will directly or indirectly affect its interests. An early consultation with the representatives of the profession is therefore desirable.

#### INTERNATIONAL CONGRESS OF THE HISTORY OF MEDICINE

On July 18th, exactly two years after the Congress at Geneva, the sixth international Congress of the History of Medicine opened at Leyden where the meetings were held on that and the two following days they were then transferred to Amsterdam, and the meeting ended on July 23rd. The Congress was formally opened by H. P. H. Prince Hendrik of the Netherlands after addresses had been delivered by the President Dr. J. G. De Lint, lecturer on the history of medicine in the University of Leyden, and the delegates of the various countries. Nearly two hundred members in all were present from Austria, Belgium, Denmark, Egypt, Finland, France, Great Britain, Germany, Greece, Holland, Italy, Morocco, Norway, Poland, Portugal, Prussia, Spain, Sweden, Switzerland, and the United States,

<sup>1</sup> *Brit. Journ. Exper. Path.* 1917 viii 123.

<sup>2</sup> See *BRITISH MEDICAL JOURNAL*, Aug. 1<sup>st</sup> 1915 p. 225.

representatives from Germany and Austria were present for the first time. Owing to the simultaneous meeting of the British Medical Association at Edinburgh there were only a few representatives from this country, but nearly all played an active part in the proceedings. Dr Charles Singer, as the official delegate of the British Government, delivered an address at the opening ceremony, Sir D'Arcy Power took the chair on the second day and read a communication by Mr C J S Thompson, who was unable to be present, on Boerhaave's prescriptions for English patients, Dr J D Rolleston contributed a paper on St Blaise, physician and martyr, and was chosen by lot to propose the health of the ladies at the banquet. The outstanding personalities in the Congress were the veterans, Professor W H Welch of Baltimore and Professor Karl Sudhoff of Leipzig, who, by the active part which they played in the scientific and social life of the Congress, roused the admiration and envy of the younger members. Space does not permit even a brief account of the ninety odd papers communicated to the Congress. Suffice it to say that, while a considerable number dealt with Boerhaave and Dutch medicine, a great variety of other subjects were discussed. Among those that may be mentioned were those on medical folk-lore by Dr van Andel, on St Sebastian by Professor Sigerist of Zurich, on the gynecologist Luit Noeggerath by Dr Diepgen of Freiburg, on the evolution of medical philosophy by Dr Delmar of Louvain, on Dutch students in Italian universities by Professor A Castiglioni of Padua, on a Catalan plague tract by Dr A Klebs, on Dr Oliver, the Bath physician, and the biscuit that goes by his name, by Dr L B Krumpholtz of Philadelphia, and on the teaching of medical history in the United States by Dr Victor Robinson of New York. The meetings were, on the whole, well attended, and the discussions animated. Special addresses were also given on the history of the treatment of nervous and mental disorders by Dr C U Ariens Kappers, on the work of Leeuwenhoek and Swammerdam by Drs A Schriebeek and W H van Steers, on the doctors in Canaries by Mr C Veeth, and on the bier of the surgeons and druggists preserved in the church at Wolkum by Dr J B F van Gils. A collection of Dutch physical instruments of the seventeenth, eighteenth, and commencement of the nineteenth centuries was brought together in the physical laboratory at Leyden, where an excellent preliminary address was given by the assistant director, Dr C A Crommelin, who showed contemporary portraits of Huyghens, Musschenbroek, and others. Credit is also due to Drs Nuyens, de Feijer, and van der Hoeven for their admirable collection of pictures, sculpture, books, and manuscripts relating to medicine in the Municipal Museum at Amsterdam. It was only fitting that during the stay of the Congress at Leyden homage should be rendered to the memory of Boerhaave, who was the most eminent physician and clinical teacher of his age. Visits were paid to his tomb in the Peterskerk, a memorial tablet was unveiled on the wall of the house where he died, and a wreath was placed on his statue in one of the principal streets of Leyden and in appropriate address given by Professor Welch. The social festivities, for which the organizing committee deserve the highest praise, included receptions by the burgomasters of Leyden and Amsterdam, by the Minister of Public Instruction at The Hague, by Mr and Madame Fokker at Boerhaave's house, and a tour on the Zuyder Zee, including visits to Enkhuizen, where the members were entertained by the mayor and inspected the Surgeons' Hall, and to Volendam. A visit to the diamond-cutting factory was also arranged for the ladies, who were accompanied by several members of the Congress. The Congress terminated on Saturday evening with a banquet at Vondel Park where speeches were delivered by the President of the Congress, Dr Tricot-Rouvi of Antwerp

(President of the International Society of the History of Medicine), and Dr Crippon, the President-Elect of the next Congress. This will be held at Rome in 1930, but in 1928 the International Society of the History of Medicine will take part in the Congress of Historical Science to be held at Oslo.

#### INFECTIOUS DISEASES IN BULGARIA

BULGARIA, owing to its geographical position, is exposed to the pestilences which come from the East. It has quarantine stations at Varna, Burgas, Silvelgrad, and Rustchuk, together with thirteen health posts elsewhere. Infectious disease within the country, as stated in a recent paper, is controlled centrally by a director of public health, and locally by medical officers and sanitary inspectors, aided by provincial and district councils. For plague, cholera, small-pox, typhus fever, and relapsing fever hospital isolation is obligatory, for enteric fever, scarlet fever, and diphtheria it is not unusual, other infectious diseases are treated at home. In home isolation the house is placarded, access forbidden, and a gendarme or watchman placed on guard. There were two cases of plague in 1924 but cholera has not occurred since 1916. Small-pox has become comparatively rare. Vaccination in the first year of life is compulsory, and must be followed by two revaccinations before the ages of 7 and 20 respectively. All contacts with small-pox must be vaccinated or revaccinated, and general vaccination, under conditions, may be imposed during outbreaks. In 1919 there were 8,746 cases of small-pox, in 1923 there were 20, mainly refugees and Turks. Typhus was imported from Serbia in 1914, and in 1917 there were 6,697 sick. Since that date its prevalence has declined, but in 1923 there were 413 cases with 51 deaths. Enteric fever is frequent in the poorer districts where wells are unprotected, flies numerous, and life in general unhygienic. Scarlet fever is widespread. In 1923 there were 15,585 cases with a case mortality of 18 per cent. The type of disease is severe and its treatment inadequate. Measles is prevalent but generally mild, and diphtheria is sporadic. Rabies is endemic in Bulgaria among domestic and wild animals, and the number of people bitten is increasing year by year. In 1923 the antirabies section of the State Institute of Bacteriology at Sofia treated 3,429 persons, of whom 3,171 had been bitten by dogs, 101 by cats, 3 by wolves, 14 by human beings, and the rest by other animals. In some declared infective rabid animals and their animal contacts are killed. Dogs must be muzzled and wear collars with identity badges, they must be kept on the chain at home and taken out on the lead, luxury dogs are heavily taxed and all strays are killed, from fifteen to twenty people die each year of hydrophobia. Tuberculosis is not notifiable but the annual mortality from all forms in fifty towns has recently ranged from 2.4 to 3.5 per 1,000. The disease has a rising incidence in Sofia, and is beginning to invade the rural districts. Its spread is ascribed to the introduction of schools and factories. Malaria is very common, is not notifiable, but in 1922, of 23,863 school children examined in selected areas, 8,839, or 37 per cent, had splenic hypertrophy. Mosquitoes thrive in this land of lakes and marshes. *Anopheles maculipennis* is widely distributed and *Myzomyza pseudopictus* swarms in place of *1. bifurcatus*, however, is rare. Curative quinquina intermittent, oiling is usual, and effective drainage on the large scale financially impossible. Venereal disease appears to be rare. During the year 14 per cent of the army had syphilis and 20 per cent gonorrhoea, many men mobilization had to be sent home still infective. Epidemics of civilian syphilis are recorded. In one village 45 per cent of the inhabitants were syphilitic, in another 62 per cent. In towns the disease is spread by the usual channels, in the country by the use of one common feeding bowl and drinking vessel at meals. There is no leg

for venereal disease, but not prostitutes are supervised Bulgaria has a surface of some 40,000 square miles and a population of 5,000,000, of whom one-half are engaged in agricultural pursuits. It possesses various minerals, but their development is in its infancy. The country was greatly impoverished by the European war. Its public health service, as is to be expected under such conditions, is crippled by a shortage of personnel and equipment. Despite the above progress has been made, as the above observations show, but what remains to do will present to the public health administration of Bulgaria a sufficiently formidable task.

#### TRUDEAU SANATORIUM

EXCEPTIONAL activity in all departments is recorded in the forty-second annual report of the Trudeau Sanatorium, at Saranac Lake in the Adirondacks, for the year ending September 30th, 1926. More patients were dealt with than in any previous period, and the increased number of the infirm beds enabled many patients with advanced disease to undergo treatment. There was much renovation of the existing buildings, and the new animal house and bacteriological cottage were completed and opened, additional roads were constructed, and the general equipment of the hospital was much improved. The work of convalescent patients was considerably extended, and proved a very valuable factor in their treatment. Publication was begun of a series of books containing the results of the clinical observations of physicians connected with the Trudeau Foundation. Of the results of a prolonged study of intestinal tuberculosis contained in a volume prepared by Dr. LAWRENCE BROWN and Mr. H. L. SAMPSON, roentgenographer of the sanatorium, some account was given recently in our columns, (February 5th, 1927, p. 242). The second book of the series related to the diagnosis of tuberculosis by laboratory methods, it was written by Drs. E. R. BALDWIN, S. A. PETROFF, and L. U. GARDNER, and appeared early this year. The forty-second annual medical report of the sanatorium is published separately, and appended to it are the pathologist's report and the tenth collection of the studies of the Trudeau Foundation for research and teaching in tuberculosis. It is stated in it that 2197 examinations have been made of the 1,200 school children who live at Saranac Lake, with a view to determining the age at which pulmonary tuberculosis begins. Further attempts have been made to immunize guinea pig, it has been shown that as few as five tubercle bacilli can produce tuberculosis in a normal guinea pig, and it is suggested that skin testing immunity the usual injection of 80,000 to 100,000 bacilli is too high. Other subjects dealt with are the diagnostic and prognostic significance of pleurisy in phthisis, and the progression of tuberculous lesions in the lungs. A modification of the Ziehl-Neelsen method of staining tubercle bacilli is described. The claim is made that by its use there is an increase of 5 per cent in the positive results of the examination of sputa, the bacilli appearing larger and more deeply stained while beaded and hair-like forms are scarcely ever seen.

#### SMALL POX

SICKS are not wanting here and there in England that the respect of the public for the grim type of small pox which is so prone to kill or disfigure has been appreciably reduced in recent years through the local prevalence of a milder form with an almost negligible fatality. The name of small pox in the ear of many is beginning to lose its formidable sound. As fear is relieved the need for precaution is lost sight of, and the claims of vaccination as a safeguard against the disease are slighted or passed by. This attitude, however, is quite mistaken. The pre-

valence of mild small pox implies susceptibility also to the severer type, and, rightly understood, should serve as a warning that the need for vaccination is a great as ever. It is important that the public should realize the situation, and that the medical profession should be prepared. The appearance now of two publications on small pox by Dr. W. M. WAINLYN is therefore well timed. One of the prints, entitled "To whom it may concern," is a popular address on small pox and vaccination. It describes the aspect of the disease, citing tragic instances, shows how it spreads and implicates whole families, quotes the figures of small pox mortality in England from 1841, indicates the need for prompt action, and points the value of vaccination. The other print, "The accurate diagnosis of small pox," is the third edition of a post-graduate lecture. It impresses the importance, to the doctor confronted with an obscure case, of bearing in mind the possibility of small pox. It deals with the initial rashes and the crusting stage. It discusses maturation and the prostration of onset, and concludes with the statement that, however the rash may be mitigated in its severity, its relative distribution as between face, trunk, and limbs is constant in all cases. The popular print, "To whom it may concern," is recommended to the persons indicated. It puts the position as it really is, in a straightforward and vigorous manner. The post-graduate lecture is recommended to medical men, both general practitioners and health officers. It contains useful hints for those hours of trial in which reputations are made or marred.

#### MR ALBAN DORAN

MR DORAN's many friends will regret to know that he had to undergo an operation for the relief of acute glaucoma last week, and now lies in his old hospital, St Bartholomew's, where he became a student sixty years ago. Although in his seventy-eighth year, Mr Doran's mind is as active as ever, and he recalls the fact that it was during the period of his house surgeonship in 1872 that a ward was first set aside for ophthalmic cases. Sixteen years ago, on returning from consulting practice, Mr Doran gave his voluntary services to the museum of the Royal College of Surgeons, where he prepared a descriptive catalogue of surgical instruments, which will long remain the standard treatise on the history of surgical invention. In this museum, too, there are many mementoes of him, particularly the splendid collection of anatomic models which he made while a student in the museum under Sir William Flower. He also assisted Sir James Paget in the compilation of the pathological catalogue, now being again revised by Mr Cecil Beadles and Mr T. W. P. LAWRENCE. Mr Doran has been an investigator and student all his days, and there are few professional men who possess his breadth and depth of scholarship. Our readers will hope for an early recovery, meantime they will be glad to know he is receiving the utmost attention and kindness from his old hospital.

WITH very deep regret we announce the death, on August 15th, at the age of 65, of Dr HARVEY LITTLEJOHN, Professor of Forensic Medicine in the University of Edinburgh. He had been ill for some time, and was unable to take the chair at the Section of Forensic Medicine at the Annual Meeting at Edinburgh last month.

1 PROFESSOR R. T. LEITCH, F.R.S., Director of the Division of Medical Zoology in the London School of Hygiene and Tropical Medicine, whose successful researches into bilharziasis in Egypt are well known, has been invited by the Egyptian Government to continue them next winter, and to advise on the best methods of combating the disease.

## THE CULT OF WATER CURES IN GERMANY.

Tower at Rothenburg

FOR the average Englishman his holiday is an opportunity of rest and change from his work. With the German it is different, to judge from the number of "health springs"—apparently well over one hundred—scattered throughout the country. Thousands of people flock to these springs annually, and utilize their holidays in the serious business of restoring their health. Their faith in the properties of the waters is such that in Berlin it has become fashionable to continue the cure by visiting the Zoo at breakfast-time, and drinking a glass of the accustomed water while inspecting the collection of animals. The spas are federated, together with sea-bathing resorts on the North and Baltic seas, and so-called *heil-cure-spots*, under the Allgemeiner Deutscher Bäder-Verband of Berlin. The equipment of all the spas is very complete, and mostly up-to-date, so that a large range of diseases can be treated, although each place specializes in accordance with the constituents of its waters.

### Aachen (Aix-la-Chapelle)

Aachen, being close to the Belgian frontier, is easily reached through Antwerp and Brussels. It is a commercial and industrial town of 150,000 inhabitants, but the Quellenhof hotel, with extremely well appointed baths attached to it, and the Kurhaus are situated in a large garden, cultivated and wild, in a quiet spot on the edge of the city. As a spa, Aachen has suffered recently from three crises—the occupation by the Belgians, the Separatist movement, and its former reputation for the cure of syphilis. Its hot sulphur waters are said to be of about the same temperature as the waters at Culsbad. They are used for rheumatism, skin diseases, gout, and late syphilis. It is stated to have been shown by experiment on animals that the sulphur can penetrate the skin, and blacken bismuth in the subcutaneous tissues. Douche massage is considered at Aachen to be given best by an attendant in the bath with the patient, the douche nozzle being controlled by the attendant's finger. The method of Hufsch of Berlin is in use for cases of high blood pressure. Some portion of the patient is inserted into an arm bath, a sitz bath, or a leg bath, and the temperature is gradually raised to a high degree by adding hot water through a funnel leading to small perforations in the bottom of the bath. The swelling of the limb induced by the heat is believed to deplete the internal organs and lower the blood pressure. It is suggested that bi-weekly repetition of the treatment will keep the blood pressure permanently reduced. The equipment at Aachen includes mud baths, ultra-violet light, electric baths, a Zander institute, and an inhalatorium after the fashion of Ems for nasopharyngeal treatment. Patients unable to move are lowered into the bath in an invalid chair, worked by somewhat nerve-

acking machinery. An attraction of the cure at Aachen is that bathing facilities are attached to the main hotels.

### Bad Kreuznach

Kreuznach is situated on the river Nahe, near its junction with the Rhine. The wines of the Nahe district are very good. Those who prefer water can drink from the Elizabeth spring, and bathe in radio active brine. Kreuznach claims to have been the first place at which radium-emanation therapy was applied as a recognized method of medical treatment. The radio activity is said to be derived from the porphyry in the fissures and crevasses of the neighbouring cliffs, and to contain in concentration a proportion of 100,000 Mache units, "fifty times that of the strongest radium spring in the world." In the valley near Kreuznach are the *Salinen*, where the brine is concentrated for the production of "mother lye" and salt. Kreuznach also bottles its radium water. The list of diseases treated at Kreuznach is a long one, ranging from gout and scrofulosis (a term of frequent use in Germany) to skin diseases, heart diseases, and the diseases of old age. The waters are supposed also to encourage the libido sexualis. In fact, the view taken locally is that Bad Kreuznach is an ideal resort for everyone. Like Aachen it is open all the year round, with a main season from May to October.

### Bad Münster-am-Stein

Münster-am-Stein is a charming little place close to Kreuznach, and a few miles higher up the River Nahe. It lies between the Rheingrafenstein rocks and the hills called Rotenfels. Its waters are the same as those of Kreuznach, in fact, the saline works from which Kreuznach produces its mother lye originally belonged to Münster-am-Stein. The bathing establishments were rebuilt in 1911, all the baths being now supplied direct from the springs with water which does not require artificial heating. In addition to natural thermal radium acid baths, mud baths can be obtained, composed of radio-active spring sediments. In the radium emanatorium patients breathe the gases of the springs.

### Bad Meientheim

Unlike so many German spas, which are owned partially or wholly by the State or municipality, Bad Meientheim belongs to a private company, which owns the baths, kurhaus, gardens, and four hotels. Each hotel has its own bathing establishment and equipment, and a resident physician. All the hotels are run as hotels, with freedom for the guests, and not as sanatoriums. But in the Hotel Kurhaus the hotel element predominates while in the others, such as the Kuranstalt Hohenlohe, under the capable management of Dr. Leopold, the medical supervision is more thorough. Patients in boarding houses and certain sanatoriums go to the Kurhaus hotel baths for their treatment. Bad Meientheim is the German substitute for Culsbad. Its waters are suitable for diseases of the liver and gall bladder, for gastro-intestinal diseases, for diabetes, and for obesity. Six different menus are provided in the hotels to suit different patients, and these diets are supervised by the resident doctors. Meientheim is an ancient and interesting town, situated on the banks of the Tauber, and was once the home of the German knights. The delightful medieval town of Rothenburg is within easy reach, and Würzburg, the erst-

Meientheim

of Hohenlohe and the cloister of Bronnbach can be visited. Mergentheim is a quiet spot, amidst beautiful scenery, with an able director, Herr Hengst, who has been connected with hotels in London and Cairo, and there is, perhaps, more efficient supervision of the patients than is usually the case.

#### Baden Baden

As a bathing resort Baden Baden, on the river Oos, suffers from the fame of its social attractions. It has been called the "Lido of Central Europe" and the fashionable meeting place of the elite from all parts of the world. It is a well laid out and well kept town, situated amidst the dark pine-covered hills of the Black Forest, where the wealthy can live in luxury, indulge in a little mild gambling, and, when not too much exhausted with the round of pleasure, can drop into the Friedrichsbad or the Augustabad, and experience the sensation of a "wildbad" or "bain sauvage." This name is derived apparently, from the fact that the patient sits in a shallow bath on a bed of sand, through the middle of which the warm water flows. The flow of water keeps the sand clean, the sand retains the heat of the bath. The use of this bath is often combined with a prolonged process of Turkish and steam baths, massage showers, cold plunges, and, if necessary, some Zander exercises. There is accommodation for the taking of a wildbad by family parties. The baths are under the State, the municipality runs the outside attractions, the hotels are private companies. The bathing establishments are well appointed and under the control of a very capable chemist and engineer, Dr. Brur, but one is left with the impression that the baths at Baden-Baden are only one of many side shows, less closely connected with the life of the spa than is usually the case. Baden-Baden treats rheumatism and gout, and also provides a grape cure for constipation and obesity at the end of August and in September. Owing to the mildness of the climate the season is perennial.

#### Wildbad

Though Wildbad seems to possess more "Princes' baths" than most spas, and its bathing establishment is richly decorated in Oriental style it takes its treatment more seriously than Baden-Baden. It is a little town situated in the Black Forest in the midst of magnificent scenery, on the banks of the river Enz. Here the rheumatic patient can devote himself to his wildbad, with water coming from the earth at a temperature of 94°. The effects of the water are attributed mainly to its being thermal. There is nothing noteworthy in its composition, there is less radium than in many waters and it is not thought that drinking the water is of much use. Bathing is the only important thing. The patient feels worse for the first few days of treatment, and then begins to improve, and in twenty-nine days progress is complete as far as it is possible. For nervous and excitable people it is considered better that the water should be lowered 2° in temperature by storing overnight. The visitor to Wildbad has no excitements beyond the band the scenery, a beautiful park, and much trout fishing.

#### Bad Reichenhall

Reichenhall situated in the Bavarian Alps not far from the Austrian frontier, has perhaps some of the most beautiful surroundings of any spa in Germany. It was known for its salt works in Roman times, but as a bathing place it only dates from 1845, and as this town was completely burnt down last century, no old buildings remain. The springs vary greatly in strength, but some contain as much as 24 per cent of salt. Owing to its climate and its scenery Reichenhall is prepared to treat a large variety of diseases, and equipment exists for all sorts of methods, from sun baths to Storm van Leeuwen's filtered air. The main treatments, however, are by bromine baths and by compressed air. Consequently the diseases treated are chiefly those of the organs of respiration, such as asthma and emphysema, heart disease, and some diseases of women and children. The pneumatic chamber installation is very complete, and further respiratory treatment is obtained by inhalations and by promenades in the neighbourhood of the salt-evaporating works.

#### Bad Elster

Elster in Saxony is a middle class watering place, consequently it has many homes or homes for black coated insured persons and for kraunkene on patients. Prices are reduced for some 3000 patients a year. It has a very fine modern bath house, a new wing to which has just been opened. The waters contain iron and chloride salts, and in some cases natural carbonic acid gas. Radio-active waters are also in use, but these are obtained largely from the neighbouring spa, Brambach. A specialty is made of mud baths, and in the neighbourhood of Elster there are large flats of used mud which are intended to be made use of again in twelve years' time. The diseases treated are chiefly anaemia, sundry diseases of the internal organs, and women's diseases. A short distance from the town there are open air swimming baths for men and women, and for mixed bathing. There is in Elster a very well run sanatorium owned by Dr. Kohler.

#### Bad Brombach

At Brombach near the Czechoslovakian frontier a new spa has been founded. Like Mergentheim, the establishment is under a private company which runs the baths and hotel. The waters are said to be highly radio-active and under an agreement Brombach has to furnish a daily supply of radium water to Bad Elster. Because possible of its nervous the establishment was not very impressive, and the close odour in the hotels did not add to the attraction of the place.

#### SANATORIUMS

The observer of German cure places will be struck not only by the completeness of equipment at the spas, but also by the facilities offered for other forms of treatment. Thus throughout Germany there are many sanatoriums, establishments to which the nearest approach in this country are Puthy Castle, the New Clinic in Wanders Forest, and perhaps some of the hydropathic establishments. As examples of such sanatoriums we may take Buhlerhohle near Baden-Baden, Dr. Kohler's sanatorium at Bad Elster, and Dr. Konig's clinic for asthma in Reichenhall.

The Sanatorium Buhlerhohle is situated high up in the Black Forest, and is a palatial building originally erected as a home for a dozen retired army generals. It now accommodates some fifty visitors with a new wing for thirty-five more. The sanatorium itself is a clinical establishment in which all the patients are under medical discipline. In the Kurhaus diagnosis and treatment are available from the resident doctor, but for those who do not need medical attention it is a place of recreation. All internal diseases and nervous diseases are treated very little seems to be excluded except infectious disease and insanity. Diet, hydrotherapy, sun and air baths, inhalation, massage, electricity, and gymnastics are used in treatment. The cost for board and lodging is from ten to seventeen marks a day, with an additional charge of 20 per cent in the summer season. The medical fees are fifteen or twenty marks for the first examination and thirty marks every ten days for daily visits or consultations. There are other hotels and sanatoriums under the same direction at St. Blasien and Selznach.

Dr. Kohler's sanatorium at Elster is more definitely linked to spa treatment. It consists of several villas with equipment for baths and for electric, ultra-violet, gymnastic, orthopedic, inhalation, dietetic, and psychic treatment. Attached to Dr. Kohler's sanatorium is an open air establishment for poor children suffering from scrofulosis. This home was started with a donation from the Saxe-Weissenhof Fund. The children live in a state of nudity exposed to sunlight and open air.

Dr. Konig's private clinic at Bad Reichenhall is arranged for treatment by the system invented by Prof. van Leeuwen of Leiden. The principle is to keep the patients, at all events for the night, in airtight chambers erected in their bedrooms through which dried and purified air is pumped. The so-called fresh air is collected through a large galvanized iron pipe erected among the chimney pots. This air is conducted to the basement of

the sanatorium, where it is dried over ice, filtered (presumably of soot from the chimneys), treated for the removal of halogens—also derived largely from the home fires, we imagine—and then conducted in pipes throughout the house into the closed chambers and one sitting-room. Doubtless the process removes from the air pollen and other particles, and so relieves the symptoms of hay asthma while the patient is hermetically sealed up. But why the symptoms do not return during the daytime, when the patient wanders in the streets of Reichenhall is not clear. Even if spore-proof mattresses are provided while the patient is in the clinic, it does not seem to be known what happens if he subsequently drifts into an ordinary hotel. As an article by Professor Storm van Leeuwen, describing his method, is to be published shortly in the *JOURNAL*, the matter need not be pursued here. It has only been introduced to show the extent to which unusual forms of treatment are made available.

#### SUMMARY OF SPA TREATMENT

It is evident that the facilities for treatment in Germany are very complete. The establishments, whether bath-houses, sanatoriums, or hotels, are well appointed and equipped, and the charges, particularly for travelling and in the hotels, are not high. The sanitation seems good. Social amenities and amusements are numerous, and the surroundings of most of the spas are beautiful. The treatments that can be obtained are very varied, and in most cases facilities exist for more or less extensive clinical examinations. There seems to be a tendency to standardize the equipment of the establishment, so that while at Ems, for example, inhalations and nasopharyngeal treatment are the special feature, and at Reichenhall a great display is made of pneumatic chambers, such specialization does not prevent the use of most other forms of treatment. Thus mud baths can be obtained at quite a number of spas, and if the orthodox volcanic mud is not available, there is probably a moor in the neighbourhood from which a sufficiently presentable peaty substitute can be brought.

The German spa doctor seems to use his treatment intelligently. He is naturally prepossessed in favour of the water of his district, he is inclined at times to over-estimate its effects. In many cases he is not particularly given to self-questioning as to the rationale of his treatment, on the other hand he has discarded many of the less justifiable allegations of effects formerly attributed to water cures. He is ready to admit the value of the psychological results of regimen and environment on the patient. After all, the "health-springs" have been kind enough to choose as their outlet from the earth some of the earth's best beauty spots. If the seeker after rest and change finds it necessary to vary the enjoyment of scenery with the definite pursuit of health, the provision of water and mud baths, light cures, Zander exercises, and inhalation for gases from radio-active springs may well add to the benefit he receives. The advantages of these forms of treatment do not seem to require the same amount of confirmation as may be thought necessary in the case of the fresh air taken from amongst the chimney-pots.

#### GENERAL IMPRESSIONS OF GERMANY

A few general impressions derived from a tour in Germany may be recorded. It would appear that economic conditions are rapidly improving. Poverty is not visible, though it is said that many in the middle classes who drew incomes from investments were wiped out during the period of inflation. What has happened, apparently, is that, having lost their savings, those who were fit for it have taken up various occupations. Everyone seems to be working fairly hard, though there is some resentment that the products of this labour should go to satisfy the whims of the Dawes plan. During a visit to a factory two points were noticed. Some work, which looked as if in America it would have been done by machine, was being done laboriously by hand, secondly, all the workmen had a sulky and somewhat dissatisfied appearance. Both these impressions may have been erroneous. At the spas the average German is a cheerful person, by no means as fat as he used to be represented. In fact, the typical fat German *frau* seems to have disappeared. She has become

short-skirted and shingled, like the women of other countries, though shingling is by no means so universal as in England. The number of Germans who speak English is very large, and it was startling to meet a German doctor who had never been in England, yet spoke perfect English and had read the whole of Shakespeare twice, many of the plays five times, knew Mrs Gaskell's *Cranford*, and quoted Byron at length.

It is quite rare nowadays to meet any German in uniform, except policemen and sweeps in top-hats. One of the most complete changes brought about by the war must have been the disappearance of universal conscription. Probably the average German is rather pleased at being relieved of the obligation for service, apparently he is turning his attention more to sport. Some games, however, do not seem to attract the German, and golf is mainly an amusement for foreigners. To the visitor there is little evidence of the existence of restrictions to his freedom, notwithstanding the number of police regulations that are supposed to exist. It is true that in Reichenhall smoking is *verboten* in many unexpected places, but the prohibition is probably intended for the comfort of the bronchitic and emphsematic patients.

The German is quite ready to talk about his aspirations. He feels very keenly about the Danzig "corridor," and is quite convinced that it has got to be abolished. He is equally convinced that Austria will not be able to stand without him, and must come into his republic. He does not appear to want either the Kaiser or the Crown Prince back, but large numbers of the South Germans are said to be in favour of the return of Prince Ruprecht. As it is felt that the German must have room in which to expand, there is a slight hope that England may restore some of the German colonies, but as this hope may be doomed to failure it is regarded as possible that the German may set about developing Siberia, in order to make it a second Canada. In the meantime it is said that quite a number of Germans are emigrating to the colonies of other countries.

## Union of South Africa.

[FROM OUR CORRESPONDENT]

#### HOSPITAL SURVEY COMMITTEE

REFERENCE was made on March 26th (p 591) to the appointment by the Minister of Public Health of a committee to make a hospital survey of the Union, and to investigate the hospital requirements of each of the provinces. The committee consisted of Sir Edward Thornton, Director of Medical Services, Union Defence Forces, and assistant health officer for the Union—chairman, Dr A H Lowy, superintendent of the Pretoria General Hospital, Mr J R Booth, secretary of the Kimberley Hospital, Mr R F Smithers, Public Service Inspector, and a lay representative in each of the four provinces, nominated by the administrator of the province. This committee's report has now been published. It confirms the finding of the Hospitals Committee appointed two years ago—that the accommodation at most public hospitals is utterly inadequate, particularly in regard to provision for the coloured and native races. The shortage of hospital beds in the Union now is even greater than it was in 1925, only in Johannesburg has there been any appreciable improvement.

There are in the Union at present one and a half million Europeans and six million non-Europeans. The population is most dense in Natal, with 44 to the square mile, and least so in the Orange Free State, with only 13 inhabitants to the square mile, Transvaal has 21, and Cape Province 17 inhabitants to the square mile. In South Africa the density of the population is not a good indication of the amount of hospital facilities required. This depends very largely on the constituent elements of the population. The raw native living in the heart of Natal or the Transkei obviously does not require the same proportion of hospital bed accommodation as the European, and even among Europeans the demand varies. The old Boer on the farms has a fearful distrust of hospitals, thus the demand for

European hospital accommodation is relatively small in the Orange Free State, whereas in farming communities comprised mostly of members of the other dominant race the demand is large. Only along the mines of the Witwatersrand can the hospital accommodation provided for natives be considered reasonably adequate. Only good hospitals are also maintained by some of the sugar estates in Natal, and by the diamond mines and larger collieries. The Witwatersrand mines are required by law to provide one bed for every forty natives employed, but it is not unreasonable as the committee found that over 2 per cent of the average number of natives employed are constantly in hospital. On the Natal sugar estates hospital accommodation is required in the proportion of one bed for every 200 employees.

Since the demands vary so greatly in different parts of the Union, the committee recommends varying ratios of bed accommodation to population for Europeans and non-Europeans in different parts. It recommends the division, for hospital purposes, of each province into a number of central hospital areas—the province of the Cape of Good Hope being divided into six such areas, and the provinces of the Transvaal, Natal, and the Orange Free State each into two. The ratio of bed accommodation to population to be aimed at in the public and private hospitals for acute medical and surgical cases, and maternity provision is shown in a table. For non-Europeans the ratio is one to 700 of population in the whole of the Union except the Cape Western area—in which the non-European population consists largely of Europeans whose degree of civilization often approaches closely to that of European—for this area the ratio given for non-Europeans is one bed for every 375 of population. For Europeans the ratio of desirable bed accommodation to population arrived at varies from one for every 200 in Natal to one for 350 in the Orange Free State. In the Transvaal and three of the Cape areas it is one for every 250, in the Cape Western area it is one for 275, and in the Cape Midlands one for 300.

The approximate total accommodation at present available in public and private hospitals for surgical, medical, and maternity cases—excluding the beds in military prison, chronic infectious disease, and mental hospitals—for all four provinces of the Union is 5 002 European and 9 113 non-European beds. The existing ratio of beds available for communities is given as follows for Europeans and non-Europeans respectively, for the four provinces:

Cape of Good Hope	479 and 233
Transvaal	2 and 2 631
Natal	160 and 1 63
Orange Free State	845 and 7 695

For non-Europeans the actual ratio in all provinces there fore falls very far short of the theoretical ratio suggested by the committee.

Except at a few places no medical or nursing service whatever is available for natives living under tribal conditions in the native reserves and locations. There the witch-doctors and herbalists flourish, teaching the people that sickness is the result of witchcraft, and that they alone are able to cure the sick. In times not a long past, when no breath of doubt interfered with his practice the witch-doctor smelt out the supposed offender, the procedure generally ending in the torture by fire or stinging ants, and in the death of the accused person—in addition to the confiscation of his cattle and property. The witch-doctor had great value in war when he could bewitch the enemy and give invincible power to his tribe, enabling them to overcome even the white people. When tribalism continues the power of the witch-doctor has been little if not fed with. The only serious effort to break down his influence was made by Sir George Grey in 1853 when he founded the Grey Hospital in Kingwilliamstown, this was intended to be one of several hospitals in the native areas of the old Cape Colony. His scheme was however abandoned when he left the colony. Since his time little attention has been paid to the personal health of the natives in the reserves and locations in any of the areas now forming the Union.

Apart from the punishment of serious crimes, the collection of taxes, and the suppression of serious outbreaks of

epidemic disease, the tribes have been left alone as long as they lived peacefully. Much private and public money has been spent in educating and bringing Christians to the people, but their bodily health has been left largely to be cared for by witch-doctors and herbalists, the latter are officially recognized, and over 1 250 of them are still housed by the State in Natal at £3 a head per annum. When the Kaffirs leave the native area at the call of the mining industry they are not cared for medically, large numbers are actually being treated in mine and other hospitals. These are chiefly Kaffirs who have left their wives for work, and who are unable when ill to proceed home. Dr Morledge, in charge of a mission hospital in Zululand, emphasises in a recent report the urgent need for native hospitals. He describes the torture that native women must still in many cases undergo during labour. All the neighbouring women crowd into the patient's hut. Some old women may think that progress is no fact enough, and will then tie the girl tightly about the abdomen or squeeze it with her hands, if this is ineffective she kneels or stamps on the patient. Needles to relieve the pain of the child and mutilation of the mother are common sequelae. The committee expresses the opinion that the European section of the community has sadly neglected its duty to these people. It is convinced that the policy inaugurated by Sir George Grey but long since forgotten, or bringing European medicine within the reach of tribalized natives, could meet their great outstanding need, and all available native funds should be directed for this purpose.

It has been suggested that the best way of relieving the desired end would be to give facilities for the training of natives as medical practitioners. Recently a committee considered the best methods of giving such facilities for training should it be decided on. The qualified native practitioner is however rarely content to practice among his own people in the tribalized condition. Only last month grave embarrassment was caused in the administration of a public hospital by a native practitioner treating paying European female patients therein. The present committee is therefore convinced that the medical needs of the tribalized natives will not be met by providing for an influx of natives into the medical profession. It recommends the introduction of a system of dispensaries and hospitals similar to that of French West Africa. While emphasizing the fact that they do not advocate the creation of a class of native practitioners with inferior medical qualification, they believe that the problem in South Africa can best be met in the first instance by the training of a large number of native nurses and midwives. Such persons would then be available to carry European medicine to the heart of the native area, and there would be created a number of health centres working for the benefit of the people. The committee urges that no new licences for native herbalists be granted, and that all existing licences be withdrawn in any district as native nurses and midwives are posted to such a district. The herbalists would then be entirely eliminated during the next five to ten years.

The report of the committee has been well received by the daily press. In the Cape it is described as an able and courageous document giving a more vivid and arresting account of the plight of the natives than did the report of the Hospitals Committee of two years ago. The public and Parliament should bear in mind this time in such a form that they would have to take notice. Its chief virtue lies in the businesslike way in which it sets down a reasonable and exact standard for hospital bed accommodation in the Union, and then applies that standard to the position in the four provinces, and in the various hospital units into which it divides the territory of each province.

#### LEPROSY RELIEF ASSOCIATION

Mr Frank Oldrieve, general secretary of the British Empire Leprosy Relief Association, has just completed a tour of the Union. He visited all the leprosy institutions and gave lectures in the larger towns. For the lectures he made use of a cinema film entitled "Leprosy—the Great Scourge," and numerous lantern slides. His best

meeting was held in the City Hall, Capetown, when several hundred people attended. That audience included thirty-five members of the First Moslem Division of the St John Ambulance Brigade. In all his lectures Mr Oldrieve was optimistic—rather more so than local experience warrants—regarding the results of modern methods of treatment and the possibility of eradicating the disease within a comparatively short period. Provided the cases can be discovered and treated in the early stages such eradication would appear to be reasonably possible. He proposes that compulsory segregation be discontinued and that treatment and isolation be made voluntary.

Mr Oldrieve pays a tribute to the Health Department of the Union because of its policy of discharging non-infectious lepers from the institutions on probation. Since the Department of Public Health took over the administration of leprosy matters in 1923 a total of 1,026 such patients had been liberated from South African institutions. These arrested or "hunt-out" cases were no danger to the public. Segregation of infective cases was a sound policy, but far and away the most important was to get the early cases for treatment. Mr Oldrieve has now left the Union for Rhodesia en route to England.

#### NATIVE MEDICAL PRACTICE AMONG EUROPEANS

The Mafeking nurses' trouble, to which reference was made in the *BRITISH MEDICAL JOURNAL* of June 11th (p. 1078), has been taken a further stage by Dr Molema, the native practitioner concerned, having agreed to accept payment of the costs to date in connection with the application he had made in the Supreme Court against the nurses. The nurses, through their attorneys, gave Dr Molema the assurance that they would afford his patients the same treatment and attention as patients of other practitioners, they would make no differentiation whatever, nor would they alter their attitude as long as they remained attached to the hospital, subject to the provision of the law governing the treatment of patients. A fund was raised in Mafeking to assist the nurses to pay the cost of the proceedings. The whole of the nursing staff have now tendered their resignations and, as it has been found impossible to replace them, the hospital will have to close down on July 19th. This will only be averted if legislation is enacted in the Cape Provincial Council giving hospital committees the right to exclude practitioners at their discretion. The Cape Administrator is attempting to do this by introducing an amendment to the Hospitals and Charitable Institutions Draft Ordinance. But this proposed amendment is meeting with strong opposition as being designed to exclude a particular individual.

In the Transvaal Province, where the problem of native practitioners attending European patients in hospitals has not yet arisen, legislation has actually been enacted to deal with the possibility. The Transvaal Provincial Gazette contains in a schedule certain regulations approved by the Administrator in the Executive Committee. This schedule states that

"No patient shall be admitted to hospital unless such patient is attended by a medical practitioner approved by the committee and no medical practitioner shall attend any patient in hospital unless he has been duly authorized thereto by the committee, provided that any medical practitioner to whom a committee refuses authority shall have the right to appeal to the Administrator, whose decision shall be final."

## England and Wales.

### ST THOMAS'S HOSPITAL

SIR ARTHUR STANLEY, treasurer of St Thomas's Hospital, has succeeded in arousing public interest in the structure of St Thomas's Hospital by stating in his annual report that examination of the chimney stacks has shown signs of weakness attributable to two main causes: first, the deterioration of the mortar, and secondly, the increasing vibration, which is, he says, distinctly affecting the whole of the building. The hospital, which was founded about 1200, and refounded in 1553, was erected on its present site in 1871. The greater part of it is built on made-up ground, reclaimed from the river bed when the Albert Embankment

between Westminster Bridge and Lambeth Bridge was constructed. Great care was taken at that time to provide efficient concrete foundations, "but," Sir Arthur Stanley continues, "the vibration by the heavy weight and rapid pace of increasing traffic throws a severe test on the buildings, however admirably they may have been built fifty years ago." The original architect of the hospital was Mr H. Currey, his grandson, Mr H. W. Currey, who is now the consulting architect, has stated that he called the attention of the governors to the dangers arising from vibration six years ago. Though the heavy traffic of to-day was not anticipated when the buildings were erected a bed of concrete 10 ft thick was put in, but it has proved insufficient to prevent vibration from heavy lorries, and from trams, which are as bad as lorries. He states that below the shore mud there is a bed of gravel beneath the hospital, but it is waterlogged. Although there is no immediate danger it is impossible to foresee the effect of future building operations and deep excavations near the hospital. Deterioration of mortar was to be expected, as the result of age, and can be remedied, although the work will be costly, owing to the height at which some of it will have to be done. There has also been some falling away of stonework, due to the fact that when the building was erected artificial stone had only recently been introduced, and the art of making it had not been fully mastered. Structurally, however, that is not a serious matter. In his report the treasurer states that a clinical laboratory for teaching is to be erected and that a sum of £30,000 is available for this purpose. Half of it has been contributed by the medical and surgical staff and the teachers of the school, the Rockefeller Foundation has found the rest. The average daily number of in-patients last year was 547, the excess of expenditure over income was £19,543. Mr W. R. Morris has promised the munificent contribution of £16,000 a year for the next six years and a half.

### THE ORDER OF ST JOHN AND THE BRITISH RED CROSS SOCIETY

Gratifying progress in all departments of the work of the Order of St John of Jerusalem and the British Red Cross Society is reported in the seventh report of the Joint Council, which covers the period from April 1st, 1926, to March 31st, 1927. The number of cases helped by the department of auxiliary hospitals for officers is now 17,688, the majority of the patients being ex-officers suffering from tuberculosis. Grants for beds for occupational work were given to eleven hospitals, six of which were institutions under the Ministry of Pensions. Under the emergency help scheme nearly 30,000 sick and disabled ex-service men and their dependants were assisted during 1926. The total grants approved for this work from its commencement until March 31st, 1927, amounted to £739,900, and the present average monthly provision of grants is about £7,500. Although 2,140 more cases were dealt with during the year under review than in the previous year, the total expenditure shows a reduction, and the committee anticipates that the need for this emergency relief will gradually diminish. The voluntary refund of money by those so assisted remains a very satisfactory feature, no less than £15,758 having been paid back during 1926, and over £90,000 since the commencement of this scheme. More than half a million patients have been cured by the home ambulance service since it was established, and it has been particularly helpful in the case of patients in remote country districts. Ambulance stations to the number of 376 are equipped by the joint committee of the two organizations and there are in addition fifty affiliated ambulances. During the twelve months ending March 31st, 1927, the ambulances conveyed over 109,000 persons. The mobile x-ray unit has been in constant use in the smaller hospitals in and around London, and a number of treatments have been undertaken at the homes of patients. A grant of £2,000 was made to a Leeds organization which for the past six years had employed an average of 100 tuberculous men in remunerative work. With this help additional plant was installed enabling expansion of such work as brush making and painting. In spite of a considerable falling off in some

of the sources of income during the year under review—the total amount received by the Joint Council being £56,397—the income for the year exceeded the expenditure by £335, as compared with a surplus of £630 in the previous year. It is hoped that when industrial conditions become more settled the Council's income will increase.

#### THE OUTBREAK OF LOOD POISONING IN SOMERSET

WE were enabled last week by the courtesy of Dr. James F. Black (M.O.H., Bath) to publish some particulars of the sudden and rather widespread outbreak of food poisoning in the Keynham and Bath districts. Various investigations have been carried out since then, and though they are not yet completed we are indebted to Dr. Black for the following further information. The pathologist at the Bath Royal Infirmary was able to report on August 10th that he had recovered an organism of the salmonella group from a patient sent into that institution for treatment. It was the "mutton" type of *Vertricks* bacillus. In the meantime some of the remains of the ice cream which appeared to be responsible for the second batch of cases had been sent to the Ministry of Health. On August 11th the pathologist stated that it contained *Vertricks* bacilli. The inquest on the child of 5 who was the only patient to succumb was adjourned by the Bath City coroner to enable an examination of the stomach and intestinal contents to be made. In his evidence at the resumed inquiry on August 12th, the director of the Bath Central Laboratory said that he had discovered a bacillus of the salmonella group in this material. In his opinion it was the unknown variant mentioned by the medical practitioner in charge of the case in his post-mortem certificate as being the probable cause of death. A verdict to that effect was returned. In response to the request of the Ministry of Health two samples of the feces of patients under treatment at the Bath Statutory Hospital were sent to London, and one of these was shown to contain the muton variety of *Vertricks* bacillus. Although the chain of evidence implicating the ice cream is now very strong, two points yet remain to be cleared up. The first is the presence or absence of an appropriate serological reaction in the blood of patients. This will be decided in a few days. The other is the method by which the ice cream came to be infected. In this connection the following facts are of interest. In the investigation made by the vendor at the inquest, it was found that two of his own children were ill during the week, and only one had eaten any of the ice cream, may possibly be significant. It should be added that the general conditions in regard to cleanliness and sanitation under which the ice cream was manufactured by the vendor is reported to be satisfactory, and it would seem therefore, unfair to blame him for the extensive outbreak of food poisoning which has occurred. No further deaths have taken place, and all the patients are said to be going on well. In many cases, however, the symptoms were severe and prolonged.

#### PRINCIPLES AND PRACTICE OF MOSQUITO CONTROL

THE British Mosquito Control Institute at Havling Island has issued a pamphlet prepared by Mr. John F. Marshall giving a succinct history of the foundation of the institute which "owes its existence to the success of an anti-mosquito campaign which was initiated at Havling Island in 1920 to deal with the local mosquito nuisance. The details of the organization which came into being, and some account of the work accomplished. The inception and carrying into effect of the ideas was due to private enterprise and forms an excellent example of the success which can be so achieved. The knowledge obtained will form a basis upon which similar campaigns called upon to deal with similar problems in other parts of the country may build their schemes. The subject is dealt with simply and yet in detail, and while originating in the desire to rid communities in the country of a "nuisance," the principles carried out upon the problem of mosquito control will prove of value in the bigger problem of antimalarial measures in other parts of the world.

<sup>1</sup> Principles and Practice of Mosquito Control. By John F. Marshall. M.A. F.L.S. F.E.S. Havling Island British Mosquito Control Institute 1927. (D.M.S. 810 pp. 45 55 figures 2. 6d.)

#### HEALTH OF LONDON IN 1926\*

##### School Children

In the school medical officer's report the plenum and natural systems of ventilation are compared with respect to certain schools. While plenum is judged by the carbon dioxide test was superior it was found to produce an enervating effect owing to its action on the atmosphere, especially in schools which were warmed solely by heating the air in the plenum. Although objections can be made against the plenum system it is stated to be so to have it advantage, and it is concluded that there is at present no case for its general abolition in London schools. Observation on the use of dusts on soil for school floors have been continued. There is a strong preponderance of opinion that the dampness and soiling of pavement, its two chief drawbacks, are not serious enough to weigh against the increased freedom from dust which is obtained. It is proposed to extend the method to one hundred more schools.

By arrangement with the Metropolitan Asylums Board 50 beds are available at Queen Mary's Hospital, Carshalton, for cases of poliomyelitis of three months' standing.

The number of children medically in period during 1926 was 330,395 together with 191,182 previous year found alive, and inspected. The newer system has not yet penetrated into all London houses. A number of parents obstinately refuse to obtain the treatment recommended. The attitude of resistance is most marked where dental caries is concerned. One parent wrote: "I dare my daughter's teeth to remain as they are the same Power that placed them there will make due change when necessary." And another, "What are our teeth given us but to eat with, and you wants to destroy them?" But the records in general show an improvement in the health of children during school life and an intensification of the activities of children's care in the two years immediately preceding the school leaving age. Last treatment by ionization continued. Distillation for hypertrophic rhinitis and kindred affection has been introduced.

Rheumatism was the cause of the chronic invalidity of 24 per cent of London school children in 1926, as contrasted with 12 per cent for tuberculosis. Additional provision for rheumatic children was established as from November, 1926, at Queen Mary's Hospital, Carshalton in the form of a rheumatic unit of 60 beds for cases of primary acute rheumatism with temperature and acute local manifestations but without chorea.

Other sections of interest in the school medical officer's report are those relating to open air education, sun classes, physical training, co-operation with general hospitals and other voluntary agencies, defective children and the measures adopted or in prospect for the control of infectious disease in schools. Many school nurses have attained high proficiency in the swabbing of throats for bacteriological purposes in the presence of diphtheria outbreak. The measles scheme of the County Council which is put in force when the cases of measles reported from schools approach 1,000 per week involves the seconding to measles duty of nursing staff normally otherwise employed. It was in force from November 1925 to April 1926, a period of seventeen school weeks. The schools concerned numbered 759. The hours demanded by the staff to measles work were 12,189. In future epidemics there will be extended hospital provision for the treatment of measles cases. By the agreement with the Metropolitan Asylums Board of October 16th 1926 when measles is epidemic, measles case will generally be admitted to hospital in preference to scarlet fever. The object of this scheme is to save life and prevent disabling complication.

##### Miscellaneous

The report of the Public Health Department among other things with tuberculosis health programme, general directions about protection and living home. In terms of the Milk and Dairies (Consolidation) Act, 1915, the Council's powers under Part IV of the London County Council (General Powers) Act, 1907, relating to the taking and examination of samples of milk, lapad on August 31st,

1926 Eleven prosecutions against railway companies for smoke nuisance occasioned by locomotives were instituted, and eleven convictions obtained. The chapter entitled "Main drainage" deals, among other matters, with the conversion of hand-operated storm overflow penstocks on three main sewers to the tidal flap system, and flood relief works at a number of points. The chapter entitled "Housing" recounts the progress of the Council's housing schemes. Since the war, up to December 31st, 1926, the Council has completed 15,903 houses and flats, of which 4,643 belong to 1926. Since 1894 the Council has provided accommodation for about 178,728 persons in 25,874 tenements and houses, and three lodging-houses with 1,889 cubicles. The programme of work in hand comprises 15,000 additional new houses, apart from rehousing under slum clearance schemes.

#### CENTRAL MIDWIVES BOARD

At the meeting of the Central Midwives Board for England and Wales last month, when Sir Francis Champneys was in the chair, the Standing Committee dealt with letters from the Worcestershire County Council and the Worcestershire City and County Nursing Association expressing the hope that the Board's form of keeping ante-natal notes would be simplified. The Board replied that in its opinion the training prescribed by the rules should give midwives the knowledge necessary to keep the notes indicated in the form approved by the Board, and added, that while the Board appreciated the fact that there are in practice some midwives who may not, at present, be able to keep all the notes prescribed, it hoped that any such midwives would receive adequate instruction in the matters in regard to which, at present, they lack sufficient knowledge. A communication was received from Tynemouth asking the Board to reconsider its decision to discontinue its approval of lectures at that place. The Board considered that its decision should not in any way prejudice the carrying out of the practical midwifery training at Tynemouth, and declined to alter it. A communication was also received from Dr J W Thomson of Wakefield stating that the Board's decision not to approve lectures at Wakefield in future would hamper the Maternity Hospital, and might lead to the abandonment of the scheme to build a large maternity block. The Board, in its reply to Dr Thomson, pointed out that its decision only applied to lectures, and would not in any way interfere with practical training. The Board has found occasion to call renewed attention to its memorandum pointing out that certificates submitted by candidates must not be tampered with in any way, but sent exactly as received.

### Ireland.

#### SALE OF MILK IN NORTHERN IRELAND

A BILL to govern the granting of licenses for the sale of milk under special designations, now before the Northern Parliament, provides that no person shall, without a licence granted by the Ministry of Home Affairs, sell or offer for sale milk as certified Grade A, tuberculin tested, or T.T., or use any description or designation, including or resembling these. The fee for the licence and the period of its duration will be determined by regulation, and the Ministry will have power to suspend or revoke a licence at any time. Any person guilty of a contravention of the provisions of the bill will be liable, on summary conviction, for the first offence to a fine of two pounds or any greater sum not exceeding ten pounds, and for the second or any subsequent offence to a fine of five pounds or any greater sum not exceeding twenty pounds, and, if the offence is a continuing offence, to a further fine not exceeding two pounds for each day during which the offence continues. Any authorized officer will have power to take and submit for expert examination samples of any milk offered or exposed for sale. The expression "authorized officer" means any police officer or constable having authority to act as an inspector for the purposes of the Sale of Food and Drugs Acts, 1875 to 1907, and any person authorized by the Ministry of Home Affairs. A prosecution shall not be

instituted except by, or with the consent of, the Ministry of Home Affairs. All fines recovered will be paid to the Ministry of Home Affairs.

#### CANDIDATES FOR MEDICAL REGISTRATION COUNCIL

In addition to the two candidates, Dr M R J Hayes and Dr R J Rowlette, whose candidature for direct representatives on the Irish Free State Medical Council was approved by the medical organizations, Surgeon P Hayden has entered the contest. Medical practitioners who have received voting papers are reminded that the latest date for their receipt by the Returning Officer is August 22nd.

## Correspondence.

#### THE CONSTITUTIONAL FACTOR IN DISEASE

SIR,—There appears to be a slight discrepancy in Dr Hurst's extremely instructive address on the constitutional factor in disease, published in the JOURNAL of May 7th. He states that the hyposthenic gastric diathesis occurs especially in individuals of the asthenic type with long chests and narrow intercostal angle, and that it is associated with a normal or low gastric acidity. He then states that achlorhydria is always, or almost always, present in Addison's anaemia, and gives an illustration of a patient suffering from that disease, with a short chest and wide epigastric angle—that is, a hypersthenic type—I am, etc.

Alang, Federated Malay States, June 28th

J G REED

\*We referred this letter to Dr Hurst, who replies as follows

SIR,—Dr J G Reed's letter concerning the type of individual in whom Addison's anaemia tends to develop raises a very important question. It is true that the hyposthenic gastric diathesis occurs especially in hyposthenic individuals with long chests and narrow intercostal angles, whereas the constitutional achylia gastrica which predisposes to Addison's anaemia is associated with a short chest and wide intercostal angle. In the past I have assumed that constitutional achylia gastrica is simply an exaggeration of the hypochlorhydria which forms part of the hyposthenic gastric diathesis. But, apart from the difficulty mentioned by Dr Reed, it is a remarkable fact that in many cases of constitutional achylia gastrica the stomach is short and high, very similar to that observed in the hypersthenic gastric diathesis, and in striking contrast with the long and low stomach seen in most people with the hyposthenic habitus. Moreover, the achylia gastrica of Addison's anaemia is always absolute, and extreme hypochlorhydria, which occurs sometimes in normal individuals, as well as in chronic gastritis and in cancer of the stomach, is never seen in Addison's anaemia, the contrast has become very clear since the introduction of the fractional test meal, which may show a trace of free acid in one or more fractions in cancer of the stomach, but never in Addison's anaemia.

I am therefore inclined to think that achylia gastrica is a mutation rather than a normal variation from the average, like hyperchlorhydria and hypochlorhydria, hyperpiesia and hypopiesia, and is, as I first suggested some years ago, an inborn error of secretion, strictly analogous to Garrod's "inborn errors of metabolism," such as cystinuria, alkaptonuria, and pentosuria. The error is one of function and not of structure, as the mucous membrane is normal and shows a normal number of oxyntic cells, unless secondary gastritis has occurred—I am, etc.

ARTHUR F HURST

New Lodge Clinic, Windsor Forest, Aug 11th

#### RESULTS OF TREATMENT OF UTERINE CANCER

SIR,—It is a matter of regret to me that Messrs Berkeley and Bonney (August 13th p 284) are displeased at the method employed by me on page 101 of the report referred to. The more so, because I am grateful to them for their extremely valuable paper, which I have been able to use in the compilation of the report. I am not

is responsible for the divisions into clinical classes made by the surgeons concerned, who admit to have been merely taken from their published works. The foot-note was inserted for the express purpose of differentiating Mr Bonney's figures from the others on account of the difference of basis. A separation of the figures can readily be made by my reader with the sole result of a decrease in the size of the sample. In view of the foot-note it seemed hardly necessary to offer a separate table of Mr Bonney's data alone and equally it was impossible to exclude them.

On the second point I am indebted to Mr Bonney for pointing out an obvious inaccuracy. I will not trespass on the hospitality of your columns with an explanation of the precise manner in which the error arose. One case requires deducting from the 72 being in class IV all of which cases have been deducted throughout for reasons given, leaving a total of 71 and the number alive at 5 years should be 17. This error modifies slightly certain of the percentages in the text of the report (the modifications vary from 0.3 to 1.1 per cent) which have been noted and will be corrected if and when occasion offers—I am etc.,

London W.C.2, W. L.H.

JANET L. LANE CLAYTON

### VARIATION IN THE SEVERITY OF CROUPOUS PNEUMONIA

Sir,—I am glad to see so eminent an authority as Professor J. A. Lindsay (August 12th, p. 283) referring to the variability in the virulence of infection in pneumonia and the consequent fallacies which this variability introduces when the value of different methods of treatment is being assessed. I should like to support Professor Lindsay's experience by a reference to a series of cases of lobar pneumonia which I had the opportunity to observe during the war. In two and a half years I saw 559 cases, with a mortality of 10.9 per cent. At one time 53 consecutive cases recovered, and were succeeded after one death, by another 40 consecutive recoveries. All the patients were treated under precisely similar conditions and were drawn speaking generally, from a selected population.

Professor Lindsay's experience, though naturally relating to a smaller number of cases in hospital, is perhaps the more striking because his patients must have been drawn from all sections of the population and, although spread over so long a period as two years, a number—presumably about 30—recovered, when the average mortality was as he states 20 per cent. I have previously referred in your columns (March 26th, p. 595) to this subject in pointing out that had I adopted some special or peculiar therapeutic measure at this particular time the credit for an exceptionally high a recovery rate would almost unavoidably have been given to such treatment. Yet at no time was any but symptomatic treatment employed. It seems impossible to envisage the opportunity of any one observer to test the effect of a particular form of treatment on a sufficiently large number of cases during a period so short that fluctuations in the virulence of infection could with confidence be eliminated—I am etc.,

London, N. 1, A. L. H.

ADOLPHUS ABRAHAMSON

### THE PROPOSED NEW HOSPITAL POLICY

Sir,—Mr Groves in his letter of August 13th (p. 285) says Dr Flemming, in his letter of August 6th, had if he had "overlooked the fact that the two great hospitals of this city have refused to unite in forming a common scheme for hospital reform." But this was not what Dr Flemming asked. As Mr Groves advocated State control of hospital Dr Flemming suggested that Mr Groves had overlooked the report of the Voluntary Hospitals Committee, which, it will be remembered, was strongly in favour of the voluntary principle in hospital policy being retained as was also the Hospital Committee set up by the Ministry of Health which preceded it, and this policy has been repeatedly affirmed by the British Medical Association during the last seven years. Dr Flemming states (he does not ask Mr Groves if he recalls the fact) that, at a con-

ference with a view to forming a joint committee to consider co-operation and improved organization of hospital in Bristol, Somerset and Wiltshire Bristol General Hospital by the attitude they adopted, wrecked the scheme. I do not know exactly what the scheme was, but I doubt very much if it included actual amalgamation of any hospital in the city, in distinction to co-operation in working. Mr Groves states that the Voluntary Hospitals Commission made an attempt to bring about amalgamation of certain hospitals in the city. I think this is a mistake. I do not believe it ever concerned itself with the question of the actual amalgamation of two hospitals in this city, though no doubt it favoured all efforts at hospital co-operation and improved organization.

Mr Groves expresses his great regret that amalgamation of the two large general hospitals in Bristol has not been brought about, and states that this is due to the refusal of the committees of the two institutions to agree to it. That is quite true. After the most careful and prolonged consideration—at any rate on the part of the committee or one of the hospitals—they came to the conclusion that working in separate buildings each hospital was best managed by a separate committee, and worked by a separate staff and that the amalgamation of finance was practically impossible, as very large sums had been bequeathed to each separate institution. At the same time they are perfectly willing to enter into any scheme of helpful co-operation which will improve the working of the institutions or economize their expenditure.

Then Mr Groves says we should not be content with our voluntary hospitals if only we had seen them of Toronto, Copenhagen or any of the Swiss cities. No one doubts that it is possible to construct better hospitals than many of our present voluntary ones. No doubt the comparatively new King's College Hospital is much superior in construction to St. Bartholomew's, or Guy's or the London Hospital, but it would not, therefore, be justifiable to scrap these older, but still very efficient, hospitals. As I said in my last letter if all the old hospitals were rebuilt we should undoubtedly build better hospitals but I asked: Are the existing ones so inefficient that it is necessary to abandon them? When at a meeting in London a few years ago a surgeon expressed the opinion that all hospitals built fifty years ago should be scrapped Lord Knutsford, the chairman of the London Hospital, said "that if they followed changes in architectural fashions the London Hospital might have been entirely rebuilt three or four times and even now be structurally out of date" that was in 1922. Probably the comparatively new King's College Hospital is already out of date as compared with the latest Canadian or Swiss hospital.

Mr Groves thinks I have been "hard pressed" for reasons for opposing the country hospital. I have not been "pressed" at all, the reasons for replacing the city hospitals by country ones are clear and obvious. He suggests that it is really no advantage to have the hospital in the city, even though though it may yet be several miles from the staff and students (the patient's relative). But planning that the staff and students live one or two miles from it on the outskirts of the city (certainly the patients' friends and relatives live in the city) it is clearly of much easier access to them than several miles away in the country and most probably on the opposite side of the city to that on which the suburb in which they live is situated.

Then he says there is no room in the city to extend the existing hospitals on the pavilion pattern. But if he will take the trouble to read my last letter carefully he will find that I proposed that extensions should take place in the form of country annexes with open air wards. The nurses' homes attached to the city hospitals at any rate in Bristol are not in noisy lanes but in quiet airy surroundings.

With regard to specialization I am afraid Mr Groves has misrepresented my meaning. As he expresses it I am quoted as saying it does not matter that increased specialization is better for the patients we must not have it because it will reduce the incomes of the staff. What I really pointed out was that if so many new specialists were

created, the scheme might prove unworkable, because even specialists must get sufficient income to live, and they might not if they were very numerous. A city can only support a very limited number of specialists, and if they were created in excess of this number the whole scheme would break down. I was only concerned with the amount of income made, because if it was insufficient for them to live on, as it would be if too many of them were created, the scheme would not work.

Mr. Groves says I raised a difficulty in the matter of the student's education "if all special branches of medicine and surgery are adequately equipped and properly staffed." I did nothing of the kind. I said if medicine and surgery were broken up into a number of subsections it might have a serious effect on medical education, which is a very difficult matter. I agree that the "undergraduate students of medicine must be taught the essential principles of their science and art by teachers and tutors, who combine to give an undergraduate curriculum"—it is indeed quite obvious—but I must point out that clinical teaching is one of the most important departments in that curriculum, and that the proposal further to subdivide medicine and surgery should be very carefully and critically examined in its bearing on clinical teaching—I am, etc.,

Bristol Aug 14th

CHARLES A. MORTON

#### A TUDOR SANITARY RELIC

SIR,—At Kelston in Somersetshire, about four miles from Bath on the upper road to Bristol, there lived in his great Tudor mansion the celebrated Sir John Harrington, godson of Queen Elizabeth and translator of Ariosto. This witty and somewhat Rabelian countier introduced into this country—or certainly into the great houses of this country—the water-closet. A nice pamphlet, *The Metamorphosis of Ajaar*, describes in the broadest and most humorous terms his reasons for such an innovation, and gives a sketch of his own palatial edifice for its housing. His mansion was pulled down by Sir Caesar Hawkins, and only a few remains of one of the towers still stand, built on to the churchyard, but at the foot of a garden now the property of Mr. Spence of Kelston, and closely adjoining the site of the Italian garden of the ancient mansion, I discovered the remains of the famous "pan" house, which the present owner had carefully preserved, and which corresponds with the structure illustrated in the ancient pamphlet. To all sanitary authorities I think this information may be of interest—I am, etc.,

London, W1, Aug 3rd

F. JOHN PONTON

#### ONCHOCERCA GIBSONI AND ITS POSSIBLE TRANSMISSION BY SIMULIUM

SIR,—Dr D. B. Blacklock, at the end of his article in the *BRITISH MEDICAL JOURNAL* of January 22nd (p. 129) on "The insect transmission of *Onchocerca volvulus* (Leuckart, 1893)," suggests that possibly *O. gibsoni*, responsible for the production of worm-nests in cattle in Australia, might be transmitted by some species of *Simulium*.

As one of the principals engaged some years ago in the study of *O. gibsoni* (Johnston and Cleland), and in endeavouring to ascertain its possible means of transmission, I can state authoritatively that transmission occurs in districts entirely free, so far as careful investigations showed, from any species of *Simulium*.

In one experiment the transmitting agent seemed to be ruled down conclusively to a tabanid or a mosquito. In New South Wales transmission occurs on the lower Hawkesbury River, and abundantly on the north coast near Kew, in neither place has *Simulium* so far been detected, and a very close search has been made for all biting flies. In my experience over a wide area of Australian species of *Simulium* are not widely distributed. I have only met with them myself at Bambera and on the Cranbills in New South Wales, on the Cooper in the interior of Australia, and near Hallett's Cove, south of Adelaide—I am, etc.,

J. BURTON CLELAND,

Professor of Pathology, University of Adelaide

May 28th

#### REMUNERATION OF HOUSE APPOINTMENTS

SIR,—I read with strong approval "House-Surgeon's" letter (August 13th, p. 285) urging that higher remuneration should be given to resident officers in hospitals.

When a houseman is appointed he has usually, as a student and after qualifying, devoted at least three years to clinical work, and is frequently a very competent medical man in spite of his lack of experience. He has been through an extremely long training which has, as often as not, drained the family finances.

It seems extremely unjust that a man with no financial backing should, when he has qualified, have to accept the appointment which offers him the most nearly adequate salary rather than that for which he is most suited, and which offers the best chance of his becoming a really skilled practitioner.

The less competent men quite rightly do not get appointments, and the remainder are often asked to accept only then keep in exchange for their whole-time services. Not only does the houseman agree to give up his whole time to the service of the hospital, but, with rare exceptions, he also identifies himself most loyally and wholeheartedly with the interests of the hospital. In many cases he does much routine and clerical work, which is of no profit to him professionally. Admittedly a resident officer is gaining experience. But so should any professional man at any time in his career, and still deserve more adequate remuneration than is given to the majority of housemen at present.

A scale with £150 a year as a minimum for a resident appointment seems to me reasonable.

I should further like to join with your correspondent in protesting against the pernicious practice of asking a large number of candidates to call—as it seems to me unnecessarily, and often at considerable expense—upon the honorary staff of a hospital—I am, etc.,

August 12th

HOUSE-PHYSICIAN

SIR,—From "House-Surgeon's" letter it is apparent either that he is very young indeed in his medical career or that he has overstrained his time in hospitals. He has yet to learn that the newly appointed house officer has gained a position of inestimable value to himself at a time when his actual value in knowledge and experience is in no way comparable with the theoretical value of his diploma.

A year in hospital is as indispensable as any year of his student life, and yet, instead of being called on for the payment of fees, he is provided with free board and lodging and often an additional £50 or £100. The apparent inconsistency of a larger salary being offered by a small hospital is simply an expression of the law of supply and demand, for the larger and more important hospital provides a wider experience and a recognized status in the application for further appointments. Furthermore, the mere provision of board and lodging is certainly not a negligible asset, as your correspondent will eventually find when he passes out into the hard, cold world.

The necessity for interviewing candidates in all hospitals not attached to medical schools is so obvious as to need no elaboration. Its recognition by your correspondent must be only a matter of time. The British Medical Association has already done the hospital resident a noble service by securing the payment of fees for attendance at inquiries. The regulation of salaries, however, is of much greater importance from two to ten years after qualification, and this fact has been recognized and is being acted upon by the Association. I am, etc.,

August 13th

#### "BLOOD PRESSURE"

SIR,—Over twenty years ago I purchased a sphygmomanometer. My colleagues looked on me as a fiddler. I regularly took blood pressures, and mentally condemned some of my patients to an early grave. Most of them are alive and well to day. Nowadays every doctor goes about with a manometer in his kit. A good part of my time is spent in trying to undo the links in mentality brought about by patients being told by one doctor or another that they had "blood pressure." I rarely produce my

instruments now, practically one can tell by the finger on the pulse whether the pressure is high or not. The hard whiplike feeling of the renal pulse is characteristic, and also the arterio-chronic but there is a large number of high pressure cases which are "benign," to quote a word used by Professor Lamb of Philadelphia in a letter to me about a patient of mine who had been under his care when she was on a visit to the United States.

A physician's aim in life is surely to diminish the sum total of human misery mental as well as physical and I think it is highly wise that we stored up our sphygmomanometers and refrained from exciting pain in our patients' minds—I am, etc.,

WES KIRBY, M.D.

ADAM MOSES

### MEDICAL CONFIDENCE

SIR,—The question of what is called medical secrecy is dealt with in a leading article in the *JOURNAL* of July 30th, p. 178 and I would like to put the matter in a rather different light.

This is not a question of medical privilege: it is fundamentally a question of medical honour and it is this point that seems to be lost sight of.

It is essential for the benefit of the patient that what he confides to his doctor should be kept inviolate: it is upon this assumption that he confides in his doctor, and the relation between doctor and patient is based upon the trust of the patient in his doctor. It can never be right for that trust to be betrayed. The amount of pressure has nothing to do with it, no pressure, however great, can excuse a dishonourable action.

The penitent confesses to the priest for the saving of his soul: the patient confides in his doctor for the healing of his body. To my mind the trust is as sacred in the one case as the other. If the priest accepts and keeps inviolate the trust the doctor can do no less. In the case of the confessional the problem was decided by the refusal of the priest to reveal in a court of law anything told to him in the confession. There was no legal sanction for this, there is no legal sanction to-day, but the courts learned by experience that by no threat or compulsion could a priest be forced to reveal what he deemed himself bound in honour to conceal.

I suggest that in proposing to seek legislation on this point we are approaching the problem from the wrong direction: for one reason, legislation would probably not give us what we want, for another, as the problem has nothing to do with votes, Parliament would never find time for it.

The only way to ensure that our patients' confidences are not betrayed is to refuse to reveal them without the consent of the patient: that is to say, we must fight exactly as the Catholic Church fought. No judge should be able to compel a doctor to do a dishonourable act. It is a dishonourable act to betray a trust and no words of any judge can make honourable that which is dishonourable. If a doctor is ordered to betray the trust of his patient he should refuse. It is possible or probable that he will be committed or fined for contempt of court: it is better to be so committed than to do a dishonourable action—I am, etc.,

Brighton Aug. 11

ALAN C. GEMMELL

### THE TUBERCULIN DISPENSARY BENVOIENT SOCIETY

SIR,—I should be grateful if you would enable me through the medium of your columns, to bring to the notice of members of the profession the fact that the Tuberculin Dispensary is now carrying on its work at 32 Fitzroy Street W.1. Patients may be sent for consultation and treatment on Tue-days and Fridays at 2.30 p.m.

Medical men who are interested and would care to see the work for themselves are invited to attend full facilities for seeing the patients and their records will be gladly afforded them—I am, etc.,

W. CAMAC WILKINSON, M.D.

August 15th.

### Obituary

**THE LATE DR. C. W. DANIEL.**—Dr. P. Manson Bahr has sent us the following, per mail tribute, to Dr. C. W. Daniel, of whom an obituary notice was published in our last issue (p. 287). At the death of Dr. C. W. Daniels we number of the pioneers of tropical medicine has been lost to the cause. Daniels is to be considered as a pioneer, not so much by reason of outstanding research but as guide, philosopher and friend of the London School of Tropical Medicine in the days of its infancy. It is as a teacher with a peculiarly clear, perspicuous yet practical mind that he will be remembered by his pupils now to be numbered by their thousands. As a research worker Daniels will rank as a close colleague and fellow worker with Sir Patrick Manson, an association which led to the discovery of the adult forms of *Filaria bancrofti* and *F. imarum*; those elusive nematodes which though isolated by his patient search have never been rediscovered since his original specimens were procured in British Cameroons in 1897. Daniels was not one who rushed into print and his published works, *Laboratory Studies in Tropical Medicine* (with Dr. H. B. Newham) and his *Tropical Medicine and Hygiene* (published first in 1909), both bear the imprint of long considered thought and practical experience. Daniels was a modest and retiring personality, and on this account probably was not generally estimated at his true worth, but he was a loyal, steadfast friend full of true courage and sterling devotion and never did he display these characteristics more fully than during the last eight years of suffering and gradual debilitation from a most distressing malady.

Dr. ALBERT DAVIES EDWARDS who died on July 16th at the age of 48 at his residence in Boscombe is owed his medical education at University College, Cardiff, and the London Hospital. He graduated M.B. M.S. Lond. in 1906 and in the following year obtained the diploma D.P.H. After holding public health posts in East London, Cardiff and Newport (Mon.) he was appointed assistant medical officer of health and school medical officer to Bournemouth in 1938 and medical officer of health two years later. Dr. Edwards held the special appointment of consulting medical officer of health to the Royal Victoria and West Hants Hospital. He was chairman of the Bournemouth Division of the Dorset and West Hants Branch of the British Medical Association from 1926 to 1927 and had been president of the Bournemouth Medical Society. A colleague writes Dr. Edwards was not only an able administrator, but a keen clinician, and especially a diagnostician, he read much and formed his own conclusions which were not always those most generally accepted. He was a good speaker, and always interesting. He was very fond of children as is clearly shown in his book *Children of the Poor* (reviewed in the *JOURNAL* of August 26th 1909, p. 554). His work as school medical officer and his charge of the Sanitary Hospital brought him much in contact with them and added to his happiness. In his life, however, there was much suffering and for many years his sensitive nature had to struggle against the handicap of frequent pain. To this was added fear of the return of the malady which had entailed a very severe operation eleven years before his death. Anxiety with regard to his work was often present, thus the possibility of small-pox in the town going undetected was latterly a source of much worry, inasmuch that he personally examined every case of chicken pox notified during the last few years. This anxiety coupled with increasing pain led eventually to his death.

Mr. FELIX CORLEON VINACE died at Birmingham on July 26th at the age of 69. He was educated at King Edward's Grammar School and at Queen's College, Birmingham. He graduated M.D. M.Ch. in the National University of Ireland in 1881, and became F.R.C.S. Eng. in 1886. After holding various house appointments at the Queen's Hospital, Birmingham, and the Hospital for

Women, Soho Square, London, Mr Vinnice settled in Birmingham, where his father had been a general practitioner, later he was appointed surgeon to the Birmingham and Midland Skin and Venereal Hospital. In 1897 he founded St Paul's Hospital for Skin and Genito-Urinary Diseases in Endell Street, Holborn. His interest in this hospital, of which he remained senior surgeon until his death, was very great, and he made large contributions to its support. Mr Vinnice was a prominent Freemason in Warwickshire. He was unmarried.

## The Services.

### ROYAL NAVAL MEDICAL SERVICE

An Order in Council, dated July 25th, has been issued (*London Gazette*, August 5th) directing that the number of specialist allowances shall be increased and paid at a higher rate, that the number of surgeon captains shall be increased, and certain other changes made.

**Specialist Allowances.**—The number of specialist allowances is to be increased from 46 to 60, and the subjects extended to include medicine, surgery, radiology, and hygiene in addition to those specified in the Order in Council, June 28th 1920. The rate of allowance is to be increased from 2s 6d to 5s a day, and is to be paid also to surgeon commanders holding the appointment of naval health officer.

**Charge Pay.**—Medical officers in charge of hospitals and sick quarters are granted charge pay at the discretion of the Admiralty, as follows: Surgeon rear admirals and surgeon captains 10s a day, surgeon commanders 5s a day.

**Establishment of Surgeon Captains.**—The number of surgeon captains is to be increased from 16 to 20.

**Previous Hospital Service.**—An officer who enters the service on or after July 1st, 1926, who has held for not less than one year a resident appointment as medical or surgical officer in a civil hospital recognized by the Admiralty, will be eligible to have his seniority antedated by not more than one year. This concession will not ordinarily be granted when the interval between the termination of the hospital appointment and date of entry into the service exceeds six months, a period of not more than six months spent in a non-resident appointment recognized by the Admiralty may count as part of the period of a resident appointment. The time concerned will reckon for increase of full, unemployed, and half pay while on the active list, and retired pay or gratuity on retirement or withdrawal. A temporary officer, or an officer entered for short service if transferred to the permanent list, may be granted the above concession except that the time will not count for gratuity on retirement or withdrawal. The concession may also be extended to officers entered for short service who had transferred to the permanent list before July 1st, 1926. It will be limited, however, to such an ante date of seniority as will preserve their position on the seniority list in relation to officers transferred on or after that date. Any increase in seniority thus granted will count for purposes of increments of full, half, and unemployed pay, and for promotion, but not for retired pay or gratuity.

### INDIAN MEDICAL SERVICE

The Secretary of State for India in Council on June 21st made the following amendment to the Superior Civil Services (Revision of Pay, Passage, and Pension) Rules 1924—namely: In Schedule I to the said rules, at the end of the entry relating to the Indian Medical Service (Civil) the following shall be inserted—namely: "No officer employed as agency surgeon whose basic pay exceeds Rs 1250 shall be entitled to draw the allowance authorized for proficiency in the Pashto or Baluchi language." The said rules shall have effect, and shall be deemed always to have had effect, as if they had been enacted as so amended.

### TERRITORIAL DECORATION

The Territorial Decoration has been conferred upon the following officers of the R.A.M.C. (T.F.): Lieut Colonel A. Johnstone Brown, Major H. Neville Burroughes, D.S.O. (ret.), and Major R. Ogier Waid, D.S.O., M.C.

### DEATHS IN THE SERVICES

We regret to have to record the death of Lieut Colonel Thomas Samuel Beauchamp Williams, I.M.S. (ret.). An inquest was held at Holborn on July 9th, when it was stated that he had been found a few days previously dead in his chambers in Cursthorpe Street, Chancery Lane. He was lying on the hearth, in his pyjamas, under a quilt, and near his head was a gas ring with the tap turned on. A brother gave evidence that he was unmarried, that he had no financial worries but had suffered from malaria and typhoid fever during the war and had also had a sunstroke. A verdict of *suicide* was returned, and the body was retained by the coroner. Lieut Colonel Williams was a son of the late Venerable Thomas Williams, with whom many of the members of the Society were acquainted. He was born on May 20th in New South Wales at Edinburgh, where he lived until 1891, and then moved to Australia, and near Hobart in 1901. He entered the Indian Medical Service in 1902, he received a D.S.O. in June, 1917, became a Major in July, 1921, and retired, with the rank of Lieutenant Colonel, on July 7th 1922. Most of his life was spent in political employment as an agency surgeon

in various native States, being for some years stationed at Bikanir, in Rajputana. He reverted to military duty after the war broke out, and served in Mesopotamia in 1916-18, being mentioned in dispatches in August, 1917, and being promoted as above stated, to a brevet lieutenant colonelcy. After his retirement he took up politics, and contested the Bridgwater Division of Somersetshire as a Labour candidate in 1922. On that occasion he received only 1,538 votes as compared with 11,240 for the Conservative, and 11,121 for the Liberal. In 1924 he was returned for the Kennington Division of Lambeth, with 8,292 votes, the Conservative getting 7,782 and the Liberal 5,075, but in the election of the following year lost his seat in a straight fight to the Unionist getting 14,893 votes to his 11,572. In July, 1925, he stood for the Eastbourne division of Sussex, but received only 3,696 votes, the successful Unionist getting 12,741, and the Liberal 5,366. During the Parliament of 1923-24 he was parliamentary private secretary to Mr Sidney Webb, President of the Board of Trade in the Labour Government. He was at one time member of the council of the Metropolitan Counties Branch of the British Medical Association, and had been a member of the executive committee of the Westminster and Holborn Division.

## Medical News.

THE Professional Classes Aid Council, the successor of the Professional Classes War Relief Council, continues to carry on its admirable work on behalf of the now poor and other professional men and women in distress. The British Medical Association is represented on the council by Mr Bishop Harman. The report for the year ending April, 1927, states that 738 applications had been received, and financial help had been given to 163 families. Strong points are made of assisting in education and training. Assistance is also given to tide over periods of illness. The granting of loans has been found unsatisfactory, usually they merely add to a burden of debt which is never discharged. A special appeal, aided by the British Broadcasting Company, helped to place the finances of the council for the year in a satisfactory position, and the criticism formerly made that administrative expenses were somewhat high has been met by the explanation that the staff has necessarily to devote much time to social service.

THE Fellowship of Medicine announces that from August 29th to September 10th an all day course will be provided at the Queen Mary's Hospital, Stratford, with instruction in medicine, surgery, and the specialties. At the Bethlem Royal Hospital there will be lecture demonstrations twice a week, from September 6th till October 1st, and from September 12th to October 1st at the Royal Westminster Ophthalmic Hospital an afternoon course of clinical instruction, operations, and special demonstrations. The Queen's Hospital will hold an all day course for the fortnight following September 12th. From September 19th to October 1st at the Royal National Orthopaedic Hospital there will be daily lecture demonstrations, and a special visit will be paid to Brockley Hill Country Hospital on one Saturday. At the Westminster Hospital there will be a two weeks' course from September 19th to October 1st, including medicine, surgery, and the specialties, with facilities for visiting the mental institutions connected with the hospital. Copies of the syllabus of those courses and particulars of the general course of instruction provided at the associated hospitals may be obtained from the Secretary of the Fellowship, 1, Wimpole Street, W 1.

A THREE months' course of lectures and demonstrations on clinical practice and in hospital administration for the diploma in public health will be given at the North Eastern Hospital, St Ann's Road, Tottenham, N 15, by the medical superintendent, Dr T. H. Thomson, on Mondays and Wednesdays at 4.45 p.m., and alternate Saturdays at 11 a.m., commencing on Monday, October 3rd. The fee for the course, which complies with the requirements of the revised regulations of the General Medical Council, is £4 4s. A course under the old regulations may be taken for £3 3s.

THE medical members of the Council of the Chartered Society of Massage and Medical Gymnastics have issued a pamphlet addressed to the medical profession urging the employment in massage and physical treatment of persons entitled to attach the initials C.S.M.M.G. to their names. Such persons have been through a supervised course of training and have passed an examination of a high standard. The pamphlet gives a history of the "profession of massage" in this country from the formation of the Society of Trained Masseuses in 1894 to the present time when over 5,500 Masseuses and masseuses are registered with the Chartered Society. After commenting on the importance of physical measures in modern treatment, the medical signatories to the pamphlet declare that the members of the Chartered Society "constitute as widely spread and as well informed a body of masseuses and masseurs as can be found in any country in the civilized world."

THE annual summer school of the British Social Hygiene Council was held at Oxford at the beginning of August. In attendance included representatives of many interests—scholastic, religious, social, and service—from various parts of the empire, and their contributions added to the practical value of the discussions. Professor J. Arthur Thompson gave a series of five lectures on the biological aspects of modern sociological activities. Dr. Rice expounded the contributions of psychology to the problems of sex education. Mr. F. Willis spoke on the problems of adolescence, and Mrs. Neville Rolfe on the elimination of venereal disease. Educationally and socially the gathering was considered a success, and it is hoped that in future years more medical men and educationists will attend.

LAST year legislative sanction was given in France to the regulation by laws of the *chambres d'allaitement* or day nurseries. Institutions have already been established for working women in many places. Their working has been described by Dr. G. Ichol, professor at the *Ecole des Hautes Etudes Sociales*, Paris, in the *Journal of the Royal Sanitary Institute for July*. It appears that these nurseries are either attached to the factories or established near them; mothers deposit their children in them while they are at work, and nursing mothers leave their work at stated intervals to suckle their infants. The by-laws prescribe the height and air space of the nursery, the lighting, temperature, and general cleanliness, and that a mother when she enters the nursery shall don a special blouse. The establishment is visited at least once a week by a doctor. His fees and the wages of the staff are paid by the owner of the factory, no contribution can be claimed from mothers. It is not quite clear whether it is compulsory on the employers to provide day nurseries, but their number has increased since the decree was promulgated.

THE report of the Lebanon Hospital for Mental Diseases at Asfurich, near Beirut, for the year ending March 31st, 1927, gives an interesting glimpse of the condition of mental treatment in Syria. The medical superintendent of the hospital, Professor H. Watson Smith, states that there was practically no treatment of the insane throughout the region between Constantinople and Cairo except at Asfurich, until the arrival of the British in Palestine, when a small Government hospital of 70 beds was started at Bethlehem. In Iraq and numerous other places the insane were confined in prison, sometimes in chains. The Lebanon Mental Hospital was founded by a Swiss, the late Mr. J. Waldmeier, in 1896, since then 2,877 patients have received treatment in its wards. It has now 150 beds and facilities for clinical study are provided for fourth year students and for post-graduate of the medical school of the American University at Beirut. Arrangements are made also for the holding of resident posts after qualification. The hospital is administered by a general committee in London, of which Dr. E. W. G. Masterman is chairman; there are also committees in Switzerland, Holland, and America. Copies of the annual report may be obtained from the general secretary at the London office of the hospital, 139, Marylebone Road, N.W.1.

THE Permanent International Committee on Occupational Diseases has arranged that the fourth international session shall be held at Lyons in April 1929. The subjects on which reports will be presented are silicosis, cataract of occupational origin, the endocrine system and forms of poisoning, and, if opportunity can be found, statistics of occupational diseases. Further information can be obtained from Professor Etienne Martin, of the Institute of Legal Medicine Lyons, or from the Secretariat of the Committee, Hygiene Service, International Labour Office, Geneva.

THE fifth Congress of French speaking Gynaecologists and Obstetricians will be held at Lyons under the presidency of Professor Villard from September 29th to October 1st. The questions to be discussed are the diagnosis and treatment of sterility of uterine and tubal origin, introduced by MM. Chatillon of Geneva and Donay of Paris, the indications for interruption of pregnancy, introduced by MM. Bronha of Lille and Bue of Lille, and the means of preventing separation of the mother from the newborn, introduced by M. Rhenet of Lyons. Further information can be obtained from Professor Voron, 12, Quai Tolstoy, Lyons.

A SCHOOL of medicine and dentistry has recently been organized in the University of Rochester, New York, which of course, must not be confused with the Mayo Clinic at Rochester, Minnesota. A description of the new school has been published by the Rockefeller Foundation in its seventh series of *Methods and Problems of Medical Education*. The school and hospital plans the animal house and the department of pathology are described by Dr. G. H. Whipple, the professor of pathology, and dean of the medical school, who says that the two main principles constantly kept in mind during the organization of the medical school and the Strong Memorial (University) Hospital were the necessity for the

closest physical contact between the clinics and the laboratories for the basic sciences, and the construction of a part of the highest efficiency combined with extreme simplicity of structure and the strictest economy. The school and the university hospital are close to the new college for men undergraduates, and the municipal hospital has been connected by short corridors with the university hospital. In the department of anatomy neurology is combined with histology, and the latter taught very largely by the study of fresh tissues and experimental methods. Each member of the class is asked to prepare during the first year a paper on a subject chosen by himself. It is noteworthy that lectures are given sparingly, about once a week. Attendance is, of course, voluntary. The dissecting rooms are open till 10 p.m. and the use of dissecting manuals is discouraged, the directions being given by word of mouth. Professor W. O. Tenn, in his account of the department of physiology, mentions that a generous share of the usual course on physiology is under taken by the allied department of vital economics, the activities of which are described by the director, Professor J. R. Murlin, in an article with illustrations of the energy metabolism in laboratory. There is also a department of biochemistry and pharmacology, of which Professor W. R. Bloch provides a detailed description. In his account of the pathological laboratories Professor Whipple mentions that they are open till 10 p.m. on every day in the year and asserts that the mental attitude of the student is of vastly more importance than the accumulation of large numbers of facts. The department of bacteriology includes protozoology and some phases of helminthology, and so, whilst, as Professor S. Byne Jones says, be more appropriately called that of medical microbiology, Professor W. S. McClann is devoted to the teaching of specificities as such in the medical curriculum, and therefore takes neurological and dermatological cases into the ordinary medical clinic. There is, however, a department of pediatrics under Professor S. W. Clouston, and also departments of surgery and of obstetrics and gynaecology.

A PROGRAMME of post graduate courses in Berlin during the autumn has been issued, and may be obtained on application to the Office of the International Post Graduate Courses, Kaiserin Friedrich Haus, Luisenplatz 2-4, Berlin N.W.6.

## Letters, Notes, and Answers.

All communication in regard to editorial business should be addressed to **THE EDITOR, British Medical Journal, British Medical Association House, Tavistock Square, W.C.1**

ORIGINAL ARTICLES and LETTERS forwarded for publication are understood to be offered to the *British Medical Journal* alone unless the contrary be stated. Correspondents who wish notice to be taken of their communications should authenticate them with their names, not necessarily for publication.

Authors desiring PEPPINTS of their articles published in the *British Medical Journal* must communicate with the Financial Secretary and Business Manager, *British Medical Association House, Tavistock Square, W.C.1* on receipt of proofs.

All communications with reference to ADVERTISEMENTS, as well as orders for copies of the *Journal*, should be addressed to the Financial Secretary and Business Manager.

THE TELEPHONE NUMBERS of the *British Medical Association* and the *British Medical Journal* are *ALBANY 551* and *552, 553, 554*, and *555* (internal exchange) four lines.

THE TELEGRAPH C ADDRESSES are  
EDITOR of the *British Medical Journal* *Antology Westcent, London*

FINANCIAL SECRETARY AND BUSINESS MANAGER  
(Advertisements etc.) *Articulate Westcent London*

MEDICAL SECRETARY *Midscara Westcent London*

The address of the Irish Office of the *British Medical Association* is 16 South Frederick Street, Dublin (telegrams *Reclilla Dublin* telephone 4737 Dublin) and of the Scottish Office 6 Drumshagh Gardens, Edinburgh (telegrams *Associate Edinburgh* telephone 4361 Central).

## QUERIES AND ANSWERS

### ANGIO-NEUROTIC OEDÉMA

A patient asks for hints on the treatment of an *angio-neurotic oedéma*. He has tried dietary and intestinal disinfection, among other measures.

### TREATMENT OF ONYCHIA

WE have received two replies to the question of a correspondent about the treatment of onychia, published on July 3rd. Dr. CHARLES HOLWAY OGDON (Bournemouth) recommends the following method: "Soak the fingers in very hot water then, with an orange stick, such as is used in manicure manipulation,

insert between the cuticle and the root of the nail a little ointment, consisting of equal parts of ammoniated mercury ointment, zinc ointment, and boracic acid ointment. Dr C A P. TRUMAN (Exeter) advises the use of an ointment consisting of equal parts of lead subacetate and vaseline. Dr Truman adds that the late Mr Clinton Dent, from whom he heard of the treatment, said that the more acute the onychia the more certain the remedy, and Dr Truman has found it not so efficacious in the slow creeping variety.

#### INCOME TAX

##### Depreciation Super Tax

"R A H" purchased, before the war, a new 12/18 h p car for £540. He was allowed 15 per cent of that amount, £81, for depreciation for the financial year 1926-27, but the Special Commissioners propose to ignore that allowance in assessing him to super tax for 1927-28. A further income tax allowance of £69 has been made for 1927-28, and recently "R A H" has sold the car for £14, replacing it by a 14 h p car bought secondhand for £418. What should he claim in this connexion?

\* \* \* (1) Section 5 (2) of the Income Tax Act, 1918, provides that "where an assessment to income tax has become final and conclusive for the purposes of income tax for any year, the assessment shall also be final and conclusive for the purposes of super tax for the following year." It appears to follow that the Special Commissioners should allow the £81 as for 1927-28. (2) A claim to obsolescence allowance should be made when the profits for 1927 are computed, and the amount treated as an expense of that year. The sum to be claimed is £540 less the allowances—£81+£69=£150, and also less the £14 received—that is, £540 less £164=£376.

##### Depreciation of Car

A B—One partner claimed renewal allowance for an old car and the other depreciation allowance for a new car. The inspector of taxes refuses the latter claim if the former is granted.

\* \* \* It has been decided in the courts that where the expense of renewing machines, etc., is allowed the depreciation allowance is inadmissible. The Income Tax Acts deal with the profits of a firm as one unit and we are of opinion that there is technical ground for the position taken up by the inspector. At the same time the result is inequitable—at any rate, as regards one partner—and it might be well to place the facts before the Secretary, Inland Revenue, Somerset House, W C 1, with a request that in the special circumstances the inspector might be authorized to modify the demand.

##### Three Years' Average

"M F G" bought A's practice in 1924 and B's practice in July, 1927. In the latter case he did not take over the house, nor an appointment worth £100 a year. Can he claim the three years' average and so obtain the benefit of the rising profits on A's practice and of the deduction of the former expense of running the B practice?

\* \* \* The section which gives the option to the three years' average—Finance Act, 1926, Section 29 (3)—restricts it to persons who were in possession of the source of the income during, at any rate, some part of the six years preceding the three years forming the average for the year 1926-27. As "M F G" does not appear to have been in possession of either practice prior to April, 1924, he is not in a position to claim the three years' average.

#### LETTERS, NOTES, ETC

##### QUADRUPLETS

REPORTS of two cases of quadruplets have recently been received. The first is from Dr J C FORTH RITCHIE (Bairn, Glamorgan shire), the second is from Captain J DUKE, M B (resident surgeon, Eden Hospital, Calcutta). Dr Fotheringham quotes Duke as giving the proportion of quadruplets as 1 in 371,126 births, and Captain Duke quotes J Clifton Edgar as giving it as 1 in 400,000.

Case 1—On July 5th 1926 I received a form from a R N D midwife to attend Mrs H aged 28, a multipara. On arrival I found that the midwife had delivered the patient of four children, one male and three female, all living. The placenta was expelled without difficulty and a hypodermic injection of 1 c.c. of pituitin was given. The children were rubbed over with warm olive oil and wrapped in cotton wool. The patient was up and about on the tenth day. Shortly afterwards she was again pregnant, and recently I delivered her of a male child weighing 12 lb. The quadruplets were perfectly normal and averaged 3½ lb. They were athetically fed, but, after surviving one month, all died within a few days. There is a history of multiple pregnancies in the families of both parents.

Case 2—A Hindu lady, aged 25, was admitted into the Eden Hospital, Calcutta, on May 28th, 1927, for persistent vomiting and rapid loss of weight, amenorrhoea had been present for four months. She had had two children, the younger being 3 years old. The previous pregnancies were normal. She was

extremely emaciated. The fundus of the uterus reached to the level of the umbilicus, the foetal parts and movements could be felt, but no foetal heart sounds could be heard. The urine showed a trace of albumin and marked acetone. She was kept under observation for a week, but her condition grew worse and induction was considered absolutely necessary. The slow method by forceps was adopted. On the third day pains started and four foetuses and two placentas were expelled without any complication. Three of the foetuses were male, with one common placenta, the fourth was female and had a separate placenta. The female foetus, with its placenta, and one of the male foetuses were macerated. The weights of the male foetuses were 2, 2½, and 3½ oz, and their average length was 6 inches. The weight of the female foetus was 1½ oz, and it measured 5 inches. The placenta weighed 5 oz and 3 oz respectively. After delivery the patient had fever for four or five days, but she improved rapidly and left the hospital on the eleventh day. I am grateful to Lieut Colonel V B Green Armytage, M D, F R C P Lond., Surgeon Superintendent of the Eden Hospital, for allowing me to publish this case.

##### THE ESSENTIAL OIL TREATMENT OF CHOLERA

DR JOHN W. TOMB (Mines Board of Health, Asansol, Bengal) has sent us a very long reply to the letter from Lieut Colonel G O F. Seely, I M S., published in our issue of May 28th (p. 955). Dr Tomb states that he has never claimed to be the originator of the use of the essential oils in the treatment of cholera. The prescription, known as "cholera drops," belonged to the medical department of the East Indian Railway; Dr Tomb became acquainted with it while serving as medical officer to the company, and subsequently obtained the exact formula from the then acting medical officer. A similar prescription, as he afterwards learnt, was formerly in use throughout India under the name of "Mist pro diarrhoea"; it contained the oils of aniseed, juniper, and camphor, with alcohol and ether acidified with 1 per cent sulphuric acid. Dr Tomb modified this prescription slightly by substituting oil of cloves for oil of aniseed. The only credit claimed by Dr Tomb in the matter was that he showed how the mixture could be successfully used on a large scale in the mining settlement, both as a remedy and as a preventive. The incidence of cholera in the settlement was reduced to less than 1 per 1,000, which was wholly at variance with all previous experience. Apparently it had been the custom to give the mixture in drops, Dr Tomb's plan was to administer 1 drachm every half hour until 1 oz had been given, followed by 1 drachm every hour until recovery, and as a preventive he gave 1 drachm in water twice or thrice daily. With regard to the correspondence referred to by Lieut Colonel Seely it consisted of the single question whether the 40-minim doses of the mixture mentioned by him were given in water, and his reply that he gave the oils and the pro diarrhoea mixture in half a teaspoonful of sugar.

DR N N. MATHA, of Dadar, Bombay, writing with reference to the employment of the essential oils in cases of cholera and other forms of severe diarrhoea states that an indigenous medicine named amritdhara is in great repute in the treatment of these affections, and that it contains camphor, thymol, menthol, cardamom, and cinnamon. He has found that equally good results can be obtained with the first three of these drugs, given in equal quantities, and mentions a number of cases in which they have been employed with the greatest benefit. His plan is to administer 8 or 10 minims in a gelatine capsule every two hours until the diarrhoea is checked, the interval being then increased to four hours, the diet throughout being restricted to barley water. If the patient will permit it, he also administers an intramuscular injection of 5 or 10 minims of a solution of camphor in ether. Treatment with salines should not be resorted to in the early stages, but with the onset of symptoms of collapse they can with advantage be added to the treatment with essential oils.

##### DEATH CERTIFICATION

DR SIDNEY MATTHEWS (Crawley, Sussex) writes: I am not certain for whose benefit the amended Births and Deaths Registration Act has been passed, so far as the new method of death certification is concerned. During the forty years I have been in practice I have handed the certificates to the relatives of the deceased and the matter ended. I have never had any trouble. On July 30th a patient died. I followed out the new details. On August 1st the relatives arrived to say that they had been seven miles to the registrar and no certificate had arrived. The funeral was fixed for the next day. I was compelled for the first time in my life, to give a duplicate certificate, and the friends repeated the seven miles journey. The local postmaster could only supply that the original letter "had got caught up in a newspaper, as had happened before." I would suggest that the envelopes issued by the local registrars should be marked "registered," to avoid a future extremely unpleasant situation.

##### VACANCIES

NOTIFICATIONS of offices vacant in universities, medical colleges, and of vacant resident and other appointments at hospitals, will be found at pages 34, 35, 38, and 39 of our advertisement columns and advertisements as to partnerships, assistantships, and locumtenencies at pages 36 and 37.

A short summary of vacant posts notified in the advertisement columns appears in the Supplement at page 120.

## ALCOHOL AND THE MOTORIST.

### ALCOHOLIC CONCENTRATION IN URINE AS A TEST OF INTOXICATION \*

BY

CODFREY CARTER, M.B. (Lond.), M.R.C.P. (Edin.),  
D.I.H. (Lond.)

Lecturer in Forensic Medicine, Sheffield University

As the use of motor traction has become almost universal, it follows as a natural sequence that measures have become necessary to guard the community against reckless driving and especially by persons who are under the influence of alcohol. At first sight it would appear that such cases would be few, because the danger, alike to fellow travellers and pedestrians, under these conditions is so serious that elementary instincts of precaution should operate as an overwhelming deterrent.

For a man to drive a fast-running vehicle on a public highway under present crowded conditions whilst drunk is only a degree less culpable than a drunken man being in charge of a railway engine. Disaster is sure to follow.

Since it became part of my official duties to examine all persons arrested on the charge of being intoxicated whilst in charge of motor vehicles within the city boundaries of Sheffield I have been surprised at the number of cases brought to my notice. If I may take our experience, and I think we can, as an average of conditions prevailing elsewhere, I can only affirm that there is throughout the country much undue indulgence by people in charge of cars.

Punishment after conviction should be exemplary. The Government has taken this view, and the Criminal Justice Act, 1925, does not err on the side of leniency. Indeed, many police court practitioners are of opinion that the penalties are so severe that magistrates should hesitate in finding a verdict of guilty, considering that a conviction carries with it a withdrawal of the licence for a considerable period as well as other penalties.

Personally I think the punishment as well as the penalty fits the crime, but I wish that more uniformity existed in the decisions when evidence is of a conclusive character. On one point I think we shall all agree, and that is, that in framing the Act the use of the word "drunk" was unfortunate, and would not have been used had the matter received proper consideration by Parliament. There is no statutory definition of what constitutes being drunk, and therefore all the legal, versus medical, wrangling hinges upon the interpretation placed upon the abnormalities presented at the time of arrest and subsequent examination. Had the term "under the influence of alcohol" been used many difficulties would have been avoided and the issue materially simplified. The Central Midwives Board, in framing charges, made this change, and all difficulties have since disappeared. Also the term "under the influence of drink" appears in the Children's Act of 1908 and in the Inebriates Act of 1898, and they are good and workable terms.

Safe motoring depends upon a clear and alert mental outlook. Judgement must be poised, nerve cool, and the brain in a position rapidly to assimilate immediate problems, and arrive at quick and accurate decisions. This delicate nerve balance poised as it is on the highest brain centres, is the very first function to become disordered by alcohol and long before the gross inco-ordinations and other symptoms of intoxication develop. Once the latter are in evidence, a person so affected has been running against danger signals for some time, but which his brain has been too dulled to read. In order to satisfy counsel and the magistrates that a man may be unfit to drive a

motor vehicle, even when he has more or less successfully run the gamut of the recognized tests, we have to avoid many possible pitfalls.

As a full and detailed pronouncement upon the tests to be applied, and their clinical significance, have been presented for our guidance by the British Medical Association Committee, it would be a waste of time for me to go into that subject again now. We are all more or less familiar with them, but no doubt some of us place a greater or less significance upon certain of the tests than do others, or does the Committee.

Personally I think the association of congested conjunctiva with quickness of the pulse very significant as a positive test for inebriety, and I place less value upon the smell of alcohol in the breath than does the Committee, because it only shows that some alcohol has been consumed, and not how much. Also, when vomiting has occurred the breath may have only a sour smell replacing the alcoholic odour. Consumption of more than a very small amount, either before or during motoring, is dangerous, and it is only owing to the tolerant way we have come to look upon road problems and dangers that greater re-entment has not been aroused.

As I have said, the initial lowering of the mental alertness and obscuration of judgement must always be present when there are demonstrable signs of alcoholic indulgence, and a person showing these signs is unfit to be in charge of a motor vehicle, and therefore "drunk" within the meaning of the Act.

Intoxication is, of course, a matter of degree, and passes by insensible gradations from one step downward to another. Yet it is only when a man has reached the bottom, in a decidedly mixed up condition, that counsel or bench will adjudge a man drunk. I am glad that the Association's Committee has placed the loss of power of delicate nerve control from indulgence as its definition of being under the influence of alcohol. It is a sound conclusion, and is on parallel lines with the pronouncement of a County Court judge recently given, he stated that "to satisfy him that drunkenness was present in any given case, the skill and judgement normally required in the manipulation of a motor car had been diminished or impaired as a direct result of the consumption of alcohol. The test, so defined, may be difficult to apply, but drivers should realize that even a slight disturbance of judgement and response, negligible perhaps, in social moments, may spell tragedy in the hazardous business of handling a car."

Have we any further methods than the tests we customarily use to guide us to a conclusion?

I hope it may be pardonable for me to speak for a few moments upon some work recently carried out by Dr. Southgate at the Sheffield University, and in which I took a modest part. I refer to the alcoholic concentration in urine as a test of intoxication. In its report the British Medical Association Committee says that it is of opinion that, while this work is of great value from a scientific point of view, tests depending upon examination of the urine are not practicable for the purpose nor under consideration, owing to the conditions limiting their application.

This limitation no doubt refers to difficulties which arise in obtaining and procuring samples, but I think these difficulties may be gradually overcome, and are worth applying in such serious case. An alcoholic secretes a large amount of urine and does not remain long in a police cell without voiding it. All that is necessary is to make sure that he does not pass it down the w.c. A simple mechanical contrivance can secure this, such as I described in our published communication, and to which I shall make a further reference.

It is obvious that if we can recover alcohol from the urine in estimable quantity by a quick and easily applied method we can at least assert that it has been taken by the mouth within a reasonable time prior to its collection. This disproves or the assertion, made by some on being charged either that they are total abstainers, or that they have not partaken of more than the usual couple of glasses of beer during the preceding few hours. No textbook with which I am acquainted has given a satisfactory and

\*The opening paper of a discussion in the Section of Forensic Medicine at the Annual Meeting of the British Medical Association, Edinburgh, 1927. Owing to the illness of Professor Harry Littlejohn the chair was taken by the Right Hon. Sir L. Russell.

expedient method of performing this analysis, and I would refer those who feel interested in the matter to the paper read by Dr Southgate and myself before the Medico-Legal Society in London and published in the *BRITISH MEDICAL JOURNAL* on March 13th, 1926.

We owe our present position in this matter chiefly to Mellinby and Southgate. The former has done much work on the estimation of alcohol in the blood, and carried it further to the urine, following upon the lines of Widmark and Miles, and proceeded to establish the ratio between the two. It was found that this ratio stood at the figures 1 to 1.34, showing that the renal epithelium has a selective action for alcohol in secretion. The concentration of alcohol in blood is related to symptoms of intoxication of the central nervous system, and the same applies to urine.

A number of men were experimented upon under varying conditions, and the following conclusions arrived at. They found that a man of 11 st weight drinking a solution containing 26 ccm of alcohol in one drink passes urine containing 200 cmm of alcohol in 100 ccm of urine, at its point of maximum concentration. Such a man was moderately intoxicated, and therefore unfit to drive on the road. A concentration of 300 cmm per 100 ccm of urine suggested quite definite intoxication. The results of many subsequent analyses, together with clinical manifestations in each case, were given, and these fully bore out Mellinby and Southgate's figures. Having obtained a sample of urine it should be quickly bottled to prevent alcoholic evaporation, and once it has reached the analyst a definite result can be obtained within thirty minutes—that is, in time for the opening of the courts. I should add that a Fehling's test should first be performed in order to make sure that there be no alcoholic fermentation from a glycosuric specimen.

I do wish that this examination of the urine for quantitative estimation of alcohol were more frequently applied. If those interested in this subject will study Dr Southgate's publication they will see the exact conclusion which can be drawn as regards the probable amount of whisky or beer drunk, the time within which the bulk of it had been consumed, and so materially help the court to a correct decision. I may add that as small a quantity as 30 drops of urine will suffice for the purpose of analysis, and the results are given in cubic millimetres per 100 ccm of urine.

It is advisable, if possible, to obtain two succeeding specimens, noting the interval of time between their being passed, so as to obtain the inclination of the downward curve. From this we can work backward on the chart, and determine the maximum amount that has been present at the material time preceding the arrest.

A simple device for obtaining the specimens is to clamp a receptacle (which can be easily removed) on to the wooden aperture of the waist. Another plan is a small porcelain urinal fitted into the cell wall at a convenient height. The waste pipe passes through the wall into an unoccupied cell, and discharges into a vessel placed beneath for its reception. By this method no entry into the man's cell is necessary, and a second specimen is easily obtained. Very few drunken persons, I find, will provide a specimen of urine by request. They usually make an excuse, or pass it on to the floor of the cell when alone or when the ordinary way is not available.

[Dr Criter exhibited copies of Dr Southgate's charts and commented upon their significance.]

#### DISCUSSION

Dr E. BOCEA (Cincinnati, U.S.A.) referred to the importance of having a quantitative test for drunkenness and described how the alcoholic concentration in the excretions was compared with the findings on clinical examination of 500 persons suspected of drunkenness in the Cincinnati General Hospital. The concentration of alcohol in the breath and urine was tested and compared with the degree of intoxication. The physician was called into court to sustain his evidence. Symptoms of dilated pupils and flushed face were found in less than one-third

of these cases, and were principally noted in the moderate groups, persons in a state of coma showed to a high degree constricted pupils and pallor. It was well known that some individuals were able to drink more than others. This was probably due to the delayed absorption of the alcohol and the slower rate of oxidation in persons not habituated. The concentration of alcohol in the breath was the quickest and easiest test. As soon as the disturbing factor of the alcoholic liquor in the mouth was removed the concentration of alcohol in the breath showed a fairly close relation to that in the blood as it passed through the lungs very easily.

Professor J. T. J. MORRISON (Birmingham) said the work on the subject of alcohol in the urine was of high scientific value. It proved the possibility of estimating the concentration of alcohol in the blood, and since this gave a clue to the quantity of alcohol imbibed it might rebut the plea that too little had been taken to produce the alleged effects. He did not expect that the urinary test would become generally adopted because of two practical difficulties—the obtaining of specimens, and their prompt analysis. Moreover, further investigation was required to determine the modifying effects of renal and other diseases on the excretion of alcohol. It was also a serious question whether information of this character, required without the consent or even the knowledge of a prisoner, would be admissible in all courts as evidence. It was in violation of British law that no person was bound to furnish evidence that would incriminate him. When, however, an accused person denied the charge and submitted willingly to examination the matter was on a different footing. A drawback to the procedure was the variation in the effects of a given quantity of alcohol in different persons, and even in the same person in varying circumstances. There was a wide discrepancy between a moderate drinker (still more an abstemious) and a toper. Again, in the case of the same person, alcoholic effects varied with the percentage of alcohol, with the rate of consumption, and with the degree of fullness of the stomach. In comparing different persons, the body weight was a material factor, even more influential was the degree of tolerance induced by habit. "Drunk" was so elastic a term that a rigid definition was better avoided, it connoted various mental, emotional, and muscular evidences of disturbance of the central nervous system due to alcohol, and there was no single symptom which might not also be caused by disease or trauma. "Under the influence of alcohol" was too vague a phrase for the court. Any quantity had some influence, and a single glass was taken with that purpose in view. The crucial question was how much evidence of disturbance would show the degree of unfitness to be in charge of a motor car which the court would regard as proof of drunkenness. For legal purposes the impairment of functions must be obvious, and only the composite blending of several groups of findings would convince. To determine whether a person had recently taken alcohol the smell of the breath was a ready test, subject to the well known fallacies. In all cases investigation to ascertain whether the signs and symptoms were due, wholly or partly, to trauma, disease, or malformation was essential. In a medical examination of a man accused of being drunk in charge of a motor car close observation would be made of his general appearance, demeanour, odour of breath, signs of muscular inco-ordination, and time sense relating to the previous few hours. This summary embraced many details relating to face, eyes, and dress, evidences of impaired self-control, loquacity, emotional display of shyness, anger, or irrational sentiment, disregard of social conventions, slurring of speech, clumsiness in sitting down and rising, loss of balance in picking up a coin from the floor. It was not uncommon to find that a man who was the worse for drink would be several hours out in his reckoning of the intervals of time between events of the same evening.

Dr A. ALLISON (Glasgow) said a person might be held to be drunk for the purpose of one offence but not for the purposes of another. In the present case the question which had to be decided was, Had the fitness or efficiency of the individual to be in charge of a motor car with

safety to himself and the public been diminished by his consumption of alcohol? The decision rested with the court, and it was unnecessary for the medical witness to formulate a definition of drunkenness. It was well known that certain people were affected by quite small quantities of alcohol, and there was no single clinical sign which was characteristic and which could not be simulated by disease. Each individual sign might be easily demolished during cross-examination. The medical examiner should be able to present a complete picture which would convince the judge or jury that the condition of the accused was due to indulgence in alcohol. It was necessary to eliminate symptoms due to disease, shock, or excitement. In Dr. Allison's experience the shock of an accident or arrest was often sufficient to steady the person, at least temporarily. A symptom to which he attached considerable importance was the readiness with which a person who had over-indulged in alcohol fell asleep soon after being placed in the cell. To find a man sleeping heavily ten minutes after the cell door had closed on him was a contraindication of his having suffered from shock or nervousness, and was confirmatory of signs of drunkenness found during the previous examination. It was also helpful in the cases where the man had succeeded temporarily in pulling himself together when first brought to the police station. His practice was to explain the position to the accused and obtain his consent before putting him through any tests for drunkenness. He was also informed of his right to an independent examination by a doctor of his choice. Chemical tests might give useful confirmation but would never altogether replace clinical evidence.

The CHAIRMAN (Lord Russell) considered the question more from the legal point of view, and discussed the punishment for drunkenness. In a recent debate the motion was passed that the driver's licence should be suspended for twelve months, this was later modified and the driver was allowed to appeal for the suspension to be removed after three months. With regard to tests for drunkenness, whatever evidence could be produced as to the alcoholic contents of the urine or any other tests the general appearance of the accused must also be taken into consideration. He thought the accused should be given an opportunity of having a medical man of his own choice, but that it was not necessary to warn him of the object of the examination.

Professor J. L. W. MacFARLANE (Liverpool) agreed that Dr. Carter's paper was a valuable scientific contribution but thought it hardly practicable from a police surgeon's standpoint, he doubted whether the excretions of an accused person could be tested without his full knowledge and consent. As a police surgeon he knew the difficulty of certifying borderline cases. He found that each examiner had his own tests and was able to interpret the results of his tests and form an opinion as to whether the inco-ordination of thought and action as the result of drinking alcohol interfered with the proper performance of the act involved to such an extent as to produce a condition diagnosable as "drunk." One complication was that the state of the accused was often partly due to alcohol and partly due to excitement. He emphasized the importance of time. On two occasions when examining accused persons and deciding to certify them as "not drunk" he found that after some time both became distinctly incapable of driving efficiently. In one case a man changed from having complete control of himself and became an uproarious inebriate. On the many tests for muscular co-ordination he found the most delicate was to mount a staircase when the least hint of control was indicated by swaying. Perhaps the best test would be for the examiner to be aided even by the accused person.

Dr. CARTER, in reply, said that a man knew why he was arrested and did not need to be warned of the object of the examination but he agreed that he should be allowed to send for his own doctor. He was glad to know that Dr. Bogen's conclusions tallied with those formed in this country.

## RADIOLOGY AND DIAGNOSIS OF INTRA-THORACIC TUBERCULOSIS

### THE IMPORTANCE OF RADIOLOGY IN THE DIAGNOSIS OF PULMONARY TUBERCULOSIS

BY

II. VOPPISTON DAVIES, M.D., M.Ch., F.R.C.S.,  
Medical Superintendent, Vale of Clwyd Sanatorium,  
North Wales

THE title which has been given me to open this discussion contains two subjects: (1) the importance of radiology in the diagnosis of pulmonary tuberculosis, (2) the importance of this as it affects the specialist and general practitioner. Clearly the first of them has to be dealt with before the second can be considered.

Now the diagnosis of pulmonary tuberculosis is not merely a matter of recognizing the presence of the disease, though the recognition of it and the differential diagnosis are of prime importance and are often matters of great difficulty. Diagnosis must necessarily include in addition to the type of disease, the character of it, whether, that is to say, it is acute or chronic, and to what extent the changes due to the tubercle bacilli predominate, or are complicated by or overshadowed by those due to the secondary organisms, further what part is played by the mechanical changes. Finally it is imperative especially if surgical treatment comes into consideration, to know the anatomical extent of the lesions.

While pulmonary tuberculosis may present itself with all the textbook symptoms and signs in many cases there are problems as to the extent of the activity, the anatomical areas involved, the character of the secondary changes, and the share they take in the picture which are extremely difficult to solve. The symptoms and signs vary in every case: the clinical and the radiological picture of any patient are as individualistic as are the rhinols loop, and composites on the thumb which are used for identification purposes. There may be but one symptom, such as haemoptoe or haemorrhage, there may be no sign other than harsh breath sounds. Symptoms such as cough and sputum may be absent from the picture for years. Pre-exs may be an early or late manifestation. While the symptoms are easy to ascertain but sometimes difficult to interpret, the signs may be difficult in both respects. Some patients seem incapable of using their chest or diaphragm so as to make even the normal breath sounds audible through the stethoscope. When it is remembered, further, that there is practically no symptom and practically no sign that cannot be produced at one time or another by every intrathoracic disease and that, for example, breath sounds can be heard through even a considerable layer of liquid, it is clear that there must be many cases in which it is essential that every means of ascertaining the trouble must be utilized and that it is most important in all cases to check, control and correct the clinical findings by the radiological ones.

Of all methods of investigation the clinical examination is unquestionably the most important but it does not reveal the whole truth and for much that is hidden we must turn to radiology and radiography. There are some few cases even—and they are chiefly those in which the pleural cavity is the seat of the lesion or is involved secondarily to the disease in the lung—in which one has to rely on radiology for the main part of the evidence.

Radiology has taught us a very great deal about pulmonary tuberculosis. It has corrected the one-time impression that tuberculosis starts most commonly in the apex of the lung—an impression error due to error owing to the conduction of the sounds to this region. I have taught us about the limitations of the roentgen elements of the

A paper read in printing a discussion on the Section of Tuberculosis at the Annual Meeting of the British Medical Association in Liverpool, 1917. Dr. S. V. P. Davies, M.D., M.Ch., F.R.C.S., was in the chair.

domes of the diaphragm. It has shown us how frequently the disease is more extensive than the clinical findings suggest, and, conversely, how occasionally the disease is much more limited than is suspected, owing to the widespread changes in the physical signs caused by local changes in the larger bronchi. It has also, however, helped for the time to confuse us by showing us the shadows known as "pleural rings," and those changes at the root of the lung which have given birth to the nomenclature of "hilum tuberculosis." It must be remembered that the science of radiology is still young, and that time is needed to interpret all the mysteries which the x-rays have revealed, and that it is bound to take a long while before the significance of the various shadows can be correlated with the *post-mortem* findings.

The first thing to consider is the importance of radiology in diagnosis and differential diagnosis. The cases that come before us belong to two groups: the one with few symptoms, in which the existence of pulmonary disease has to be determined, and the group with well-marked symptoms and signs, in which the character of the disease must be diagnosed. The great majority of the first group consist of children and young adults, and the commonest symptoms are cough, which has persisted since a cold or an infectious (especially measles and whooping-cough), some lassitude, poor development and dyspnoea, occasionally in the more advanced cases there is cyanosis. The physical signs are usually impaired resistance and resonance, often more on the right than on the left, deficient air entry, and some moist sounds. Quite a number of these cases are labelled hilum (or pulmonary) tuberculosis, some are treated as such, and bear the stigma for the rest of their lives. It is here that radiology has helped it first to confuse us, but will unquestionably, with increasing knowledge, prove of immense benefit.

The great difficulty lies in the inability to establish just when the hilum shadow ceases to be normal, and what are the characteristics of early disease as opposed to chronic irritation. We know that impure atmospheres lead to increase in density of shadows, that chronic irritation causes enlargement of glandular nodes and increased striation, and that in some cases, especially after bronchopneumonia, bronchitis, and also in connexion with chronically enlarged tonsils, these changes may be very striking. Among the considerable number of apparently healthy students I reviewed at University College Hospital sixteen years ago two things struck me in particular—one was the enormous irritation that occurred in the so-called normal subject (one only of these has since developed tubercle, and his original radiogram showed nothing striking), the other was that the traction of the heart to the left with a normal-looking lung and pleura was invariably due to a basal pneumothorax in the past.

In a recent paper Agassiz draws attention to the clinical picture and the radiological findings in children and young people which are the result of a non-tuberculous fibrosis of the lungs following bronchopneumonia and bronchitis, measles, and whooping-cough. He deprecates, and in my opinion rightly, the readiness with which young people with increase of root shadows and irritations therefrom are labelled "hilum tuberculosis." This term has unfortunately come into general use in much the same way as the words "influenza," "gout," and "rheumatism." It is a label attached indiscriminately and occasionally correctly. It satisfies the public because it is a definite term which can be repeated to friends and relations, it conceals the need of further investigations, ending often in uncertainty and in vague nomenclature, and it gives a sense of security, as it is as hard to disprove as to confirm. It is a label that once affixed is hard to remove. It is a term which, having been accepted and put into general use, is hard to abolish. Agassiz states that the x-ray examination "is of the utmost importance in differentiating fibrosis from other affections of the lung." The following is his description of the x-ray findings:

"It is to the shadows at the root and radiating from it that I would direct attention. These may be slightly increased with striation towards the base, or they may be dense, massive shadows extending from the level of the third to the sixth or seventh rib in front with dense striations radiating to the base

in particular, and possibly blurring or obscuring the cardio-phrenic angle or angles and accompanied in some cases by some increase of striation towards the upper lobe. All variations between these two extremes may occur. In other cases the normal reticular formation of the lung may be more evident than normal. In others again the shadows, more particularly round the hilum or upper lobe, have a honeycomb appearance, and in yet others star-shaped shadows occur.

"The diaphragmatic outline is frequently irregular, the irregularity taking the form either of undulations or, more often, of peaking. I believe that these irregularities of the diaphragm are due to other causes than that commonly assigned to them, viz., adhesions."

In the majority of the adult cases the patient comes with symptoms of a more pronounced character, and the presence or absence of disease is less likely to be the stumbling-block, but the character of the disease may be. My experience is doubtless not different from that of others. I have had many cases sent to me as suffering from pulmonary tuberculosis who were suffering from some other disease. By far the commonest mistake is bronchiectasis. Some of these patients have gone about for years, despite the persistence of a negative sputum, labelled as pulmonary tuberculosis. In many the clinical diagnosis is easy, but in some it is extremely difficult until it comes to the radiological examination. This in the majority of the cases will settle the diagnosis, but there are some very old-standing cases where the secondary bronchiectatic changes associated with chronic tuberculosis are so predominant that it is hard to differentiate between them and a non-tuberculous bronchiectasis. Less frequent types of mistake have been the labelling of cases of malignant disease and of syphilis as suffering from tuberculosis. One striking feature of these mistakes is that the cases had not been x-rayed, and, in most instances, had they been, the error would not have occurred. In this connexion three striking cases may be mentioned, even though tuberculosis did not necessarily enter into the differential diagnosis, in each case the diagnosis was made by the x-rays only. One was a case of bronchitis and emphysema in which the x-rays revealed a primary carcinoma of the lung even when found it was impossible to detect it clinically. Another was a case of diaphragmatic hernia treated in hospital for thirty years, the nearest guess made was "basal pneumothorax," until radiology cleared up the diagnosis. The third case was an elderly woman with acute pulmonary symptoms, of whose history forty years previously, when she had acute pleurisy and nearly died, I knew nothing. Not until the acute symptoms had subsided and she could be moved for x-ray examination did I realize that the lung was shrunken to about one-quarter its original size, and was separated from the shrunken chest wall by inspissated pus.

When we turn to the pleural and mediastinal cases the importance of radiology becomes even greater. We may suspect an interlobar effusion, but it is rarely more than a guess until confirmed by the x-rays, even greater is the difficulty in cases of mediastinal effusion.

In the diagnosis of activity of a tuberculous lesion it is the clinical signs and not radiology which must be relied on, though unquestionably information can be obtained from the latter source also. The snow-flake finny shadow of an acute lesion is in striking contrast to the dense, sharply defined outline of the fibrotic lesion. At times there is a great temptation to diagnose on clinical examination the presence of a cavity when the radiogram shows that the signs are due to a dense area of fibrosis juxtaposed to a large bronchus. Occasionally the radiogram will reveal a cavity in the centre of a densely fibrotic area which is unsuspected from clinical examination, the x-rays will, moreover, reveal in a large cavity the efficiency of otherwise of drainage of such a cavity, and the returned sections when present.

When the case under investigation is one with an effusion, or pneumothorax, or a combination of the two, it may be impossible to obtain by clinical examination any idea of the extent of the collapse or the character of the collapsed part of the lung. If on examination a patient is found to have a pleural effusion, it is not sufficient to be content with that as a diagnosis, it is necessary to know the cause of such effusion. It may be failing heart or kidney, trauma, suppuration above or below the diaphragm, an infection, or granuloma inside the pleural

cavity or in the lung. It may be secondary to an inflammatory lesion such as pneumonia or to carcinoma. It may be primary tuberculosis of the pleura, or secondary to pulmonary tuberculosis. The diagnosis can be easy or extremely difficult, especially if the primary lesion is in a collapsed lung surrounded by liquid. But if the liquid is replaced by air and the collapsed lung is partially re-expanded then it becomes possible not by clinical examination but by radiology to see the character of the lesion which is primarily responsible.

Information as to the presence of very small effusions, of interlobar effusions of adhesions their directions, size and number, of the nature of the lung in the region of their attachment to it and of the mediastinal pleurae are cannot be obtained by clinical examination but is revealed in part or in whole by the x rays. Take for example, the case of a basal pneumonia with imperfect resolution, a pleural effusion partly absorbed, thickening of the pleura retraction of the heart dragging up of the dome of the diaphragm and sinking in of the chest wall—a tuberculous lesion may or may not be present. This complex but common type of case can be diagnosed clinically, but as a general picture only. It is the x rays which must contribute the detail and show the relative extent of the various changes. There are two points I would like to call attention to here. I am very sceptical as to the possibility of diagnosing adhesions which exist between an expanded lung and the chest wall, some there are who claim to do this but I have not as yet had a convincing demonstration. Adhesions between the base of the lung and the diaphragm can I maintain be diagnosed if the dome of the muscle is drawn up and distorted, a shriveling lung does not distort the muscle unless adherent to it. This however, also is a controversial matter. The second point is that thickened parietal pleura is much more easily recognized by clinical examination in exceptional cases, and naturally when the seat of calcareous deposits a definite shadow is obtained due to increased opacity to the x rays. As a general rule a density of shadow attributed to thickened pleura can be proved to be due to a thin layer of liquid. The thickened pleura on the lateral surface of a partially collapsed lung can, however be clearly demonstrated.

Usually in considering diagnosis there is the extent of the lesion. It is usually more than is suspected by clinical examination. This is partly due to the fact that while some patients breathe in such a way as to bring the signs into prominence with others all the sounds are damped and muffled. Moreover in a x ray film shows deep seated lesions as clearly as superficial ones, and all the shadows are on the one plane.

Two types of case difficult at times to distinguish clinically are clearly differentiated with the x rays. I refer to patients with deficient expansion increased resistance, poor air entry harsh breath sounds and some prolongation of expiration, with possibly a few moist sounds. This picture may be due to involvement of the larger bronchi at the root, or to scattered small areas of fibrosis throughout the lung substance. I must mention also a particularly interesting case of a patient sent to me with acute laryngeal tuberculosis and the report that both lungs were free of disease. I, too, could find no clinical evidence of any disease, but the x rays revealed acute military tuberculosis of all five lobes. During the next ten weeks I could detect no signs of the disease which I knew to be there.

Occasionally the clinical and radiological evidence is to dilatation of bronchi and of cavities is inadequate. This is particularly the case in bronchiectasis and especially for lesions of the left base which are obscured by the cardiac shadow. In these cases the injection of lipiodol into the trachea and so into the bronchi and bronchioles may add a wealth of valuable information.

Precision in diagnosis is essential for determining prognosis and treatment it is absolutely imperative before any surgical treatment can be considered. To attempt treatment of a case of pulmonary tuberculosis by operative intervention without the most thorough radiological (when such is by any means available) as well as clinical examination is to make the patient run serious and unjustifiable risks. In these cases it is not so much the precise

condition of the more affected side but the character and extent of the lesion in the sound lung which is so important. In my examinations I rely entirely on the clinical examination to determine the presence or absence of active disease in the less affected lung but I turn to radiology for my evidence as to the anatomical extent of the lesion.

The value of a radiogram lies in its clarity and in our power to interpret it. An indifferent radiogram may be not only worthless but a source of danger as we may fail to detect the existence of lesions of importance, and act on the erroneous idea that they are not present. The radiogram taken with the film on the front of the chest is the most useful standard viewpoint but it may be advisable to take one with the film on the back or with the patient in the half lateral position. In some cases as in mediastinal effusions the film must be taken from the front whilst the patient assumes the orthopneic position.

I would urge that during the exposure of the film the patient be in the upright rather than the recumbent position. The former is essential when liquid is present. I would also put in a plea that the patient be screened and saved sitting down as standing may prove very exhausting to one who is sedentary and is at the same time possibly undergoing a new experience, and therefore an ordeal.

A patient should be examined with the screen, as this gives a general impression of the lesion, and information as to the lighting up of the various parts of the lung and as to the movement of the domes of the diaphragm and possibly as to the movements of shadows inside the lung. Also a rough idea can be obtained of the relatively anterior or posterior situation of a particular shadow. Screen examinations unless one waits in the darkened room for about half an hour beforehand fail to give detail and it is for this reason as well as because they afford a permanent record that radiograms should be taken.

The interpretation of the film brings us to one of the difficult problems. The radiologist who handles hundreds of films and is presumably well up in the literature can detect abnormalities and describe the shadows far better than the average medical man. Unfortunately his opportunities for studying the radiogram and the clinical picture side by side and following the development of the case are limited. The physician who specializes in pleuropulmonary diseases has very great experience but it is possibly somewhat less than that of the radiologist. He is also less aware of the allowance to be made for imperfect exposure or development but has the advantage of his knowledge of the clinical side. The general practitioner with the wide range of knowledge required of him cannot be expected to have an extensive grasp of the various subtle and complex guesses in which pulmonary tuberculosis may manifest itself nor a thorough understanding for interpretation of radiograms.

He should therefore in all obscure cases and in all those in which tuberculosis is suspected or might be by the patient and relatives recognize that the first consideration is the welfare of the patient and that to call in a specialist or consultant and a radiologist is not likely to impair his medical prestige nor cause the patient to withdraw his confidence. It is possibly partly for fear of this or of the exposure of his lack of knowledge for the interpretation of radiograms partly also on account of the expense to the patient that many general practitioners do not make greater use of the specialists and of radiology on behalf of their patients. Consequently in many cases because of the indefiniteness of the physical signs or of the difficulty in interpreting them together with the fear of alarming the patients, the general practitioner prevaricates until the progress of the disease puts all doubt out of court, such delay is however, a most serious matter as it increases to a grave degree the time required for treatment and diminishes greatly the chances of arresting the disease.

It is much to be deplored that many patients apply for sanatorium treatment for the first time only when the disease is so advanced that it is extremely difficult, if possible to counteract the spread caused during the delay. Frequently the chance of arresting the disease by medical

or surgical means, which possibly did exist six or twelve months previously, but by the time they present themselves been irretrievably lost. The chief causes of delay are

1 Postponement of treatment by the patient on account of work, finance, or aversion to the idea of entering a sanatorium

2 Non-realization of the seriousness of the condition due (a) to the doctor's opinion (a mistaken one to my way of thinking) that the patient is not equal to facing the situation, (b) to the doctor himself not realizing the extent or the seriousness of the disease. In such cases a radiogram with a report on the findings would frequently alter his conception of the case. A true realization of the state of affairs might then save the precious time and money so often wasted through the advice of "a month or two at the seaside," or "a trip to the South of France." The patient starts off without proper knowledge or guidance how he should live, and recuperates sufficiently to drag through in extra few months of work before he is once more laid low by further extension and activity of the disease.

3 Wrong diagnosis owing to an erroneous interpretation of the physical signs. If an invariable rule was made, that when there had been persistence for more than three months of symptoms which might be due to tuberculosis, the sputum (if any) was examined and a radiogram taken, many doctors would find that they returned the confidence of those patients who owing to the lack of these precautions are doomed to a lingering illness, and are often without mercy in their denunciations of the want of thoroughness in the investigation of their case.

1 The Differential Diagnosis of Non-tubercular Fibrosis of the Lungs in Children, *Tubercle*, May, 1927

## DISCUSSION

Dr E RIST (Paris) emphasized the importance of radiological examinations in connecting the clinical findings, he hoped that the time was at hand when a line would no longer be drawn between the physical signs *par excellence* and the radiological findings. X-rays were invaluable in cases with deep-seated cavity near the hilus, where often no definite focus was discoverable by percussion and auscultation, even quite superficial cavities might be overlooked by relying on ordinary physical signs, and their discovery made an enormous difference to prognosis and treatment. Only by x-ray examination had it been established that there could be transmission of abnormal sounds from the diseased to the sound lung, and it alone had given a safe method for deciding on the induction of artificial pneumothorax. In his opinion fluoroscopy was most valuable, it showed, for example, impaired movements, the inspiratory attraction of the whole mediastinum by the fibrotic lung, and the inspiratory distension of the heart shadow in bilateral fibrosis. It should always precede filming, and should be a guide to it as showing the position best adapted to display the particular feature it was desired to study in detail. This would render possible the real use of the film in indicating the minute details in morbid structure, and in obtaining a permanent and indisputable record of the condition at a given date. He pleaded for a further use of the fluoroscope in order to attain correct interpretation of x-ray findings, it ought not to be confined to the exceptional and obscure case. The clinician and the x-ray specialist ought not to communicate by written reports only, they ought to sit side by side before the fluoroscope, or, better still, the two functions should be combined in the same person. The practitioner should have free access to the x-ray room.

Dr J L STEWART (Manchester) said it could not be too strongly stated that the x-ray examination was one item in the clinical examination and did not supersede any part of it. The clinician, not the radiologist, made the diagnosis. He had found radiology of great value in diagnosis, especially in examining contacts, where the earliest definite cases were found, and where very often long-standing quiescent disease was detected by this means in older relatives of active adolescent and juvenile patients. He thought the term "hilum tuberculosis" should be given up. If the disease had reached the lung tissue the case

should be classed as pulmonary tuberculosis, if it was confined to the bronchial glands or interlobar pleura, the patients should be labelled accordingly. He believed that with extended experience, basing the diagnosis on clinical and x-ray evidence, such classification of cases would be possible. The distinction was of great importance from the point of view of prognosis, thus, it did not follow when the glands or pleura were involved, even extensively, that the prognosis was bad, and careful collection of x-ray evidence might aid in revealing the ultimate prospects in such cases. The full value of x-ray examination could be appreciated only if it was used as a routine method.

Dr J M WOODBURN MORISON (Edinburgh) said that radiology was only an extension of one of the methods of examination—that of inspection, he should like to see it included under that heading in all textbooks on diagnosis. No physical examination was complete without x-ray examination, on the other hand, a radiological diagnosis should never be demanded. The radiologist was seldom a skilled physician, and the clinician rarely had an expert knowledge of radiology, only by the close co-operation of the physician and the radiologist could the full benefit of the x-ray examination be obtained. Every young medical practitioner entering the public health service and specializing in tuberculosis should have a full course of instruction in radiology. The speaker then showed some very interesting lantern slides to illustrate the usefulness and limitations of radiology.

Dr C P LAJAGE (Manchester) described an investigation that he and Dr Bythell had carried out at the Manchester Children's Hospital on hilus tuberculosis. Excluding cases with definite physical signs, he found that the distinction between the catarrhal child and the child with early hilus tuberculosis was very difficult, a septic focus in the tonsils or nose gave toxic symptoms like those of early tuberculosis. He classified cases where possible as catarrhotoxic and tuberculotoxic. Aids in diagnosis were the history of infection, the rate of improvement, temperature and pulse tests, and the tone of the skin—especially that between the scapulae. For the treatment of tuberculotoxic cases he advocated the extension of a convalescent school system. The teaching of such patients was important, both mentally and in its effect on the physical well-being. Patients with hilus shadows who showed also symptoms such as headache, rise of temperature, frequent catarrhal infection, and general loss of tone were, if not actually tuberculous, at least potentially tuberculous. The tubercle bacillus, however it obtained entry, was always at hand to infect the site of chronic inflammation in a debilitated child, whether in a cervical gland or a hilus fibrosis.

Dr L D PARSONS (Ceylon) pleaded for the further use of test doses of old tuberculin as an aid in difficult diagnosis.

Dr MORRISTON DAVIES said he would add a final word on the difficulties ahead of those who would overstress the radiological examination as compared with the clinical side.

## THE INTERRELATION OF PHYSICIAN AND SURGEON IN REGARD TO NON-PULMONARY TUBERCULOSIS

BY

D A POWELL, M D LOND,

Principal Medical Officer, Welsh National Memorial Association,  
Cardiff

IN these days, when our therapeutics is dominated by the surgical treatment of pulmonary tuberculosis and the conservative treatment of non-pulmonary tuberculosis, the demarcation between the respective spheres of the physician and surgeon seems practically obliterated, and any discussion of their interrelation, therefore, an anachronism.

\* A paper introducing a discussion on this subject in the Section of Tuberculosis at the Annual Meeting of the British Medical Association, Edinburgh 1927.

but closer investigation soon reveals that this fusion of function in non-pulmonary tuberculosis is not nearly so complete as we have a right to expect, and have, in fact, practically achieved on the pulmonary side.

Put briefly, in non-pulmonary tuberculosis, as in pulmonary tuberculosis the physician and surgeon should be one and the same individual, embodied in the person of the tuberculosis officer or his institutional counterpart for all purposes of diagnosis and treatment, except those involving major operations or the performance of a few highly technical and specialized procedures.

To attain this end the tuberculosis officer should seize the opportunities that are now available, and train himself to become a competent surgeon, sufficiently well versed in the technique of his specialty to make a good provisional, and hazard an accurate final diagnosis, to undertake immediate treatment pending admission to an institution and to shoulder the responsibility for the care of the patient after discharge giving the general or orthopaedic surgeon his proper status of operator or final court of appeal.

This he can bring about in two ways—first by looking upon a period of residence in a surgical tuberculosis or orthopaedic hospital as quite as essential a part of his training as residence in a chest hospital or sanatorium and, secondly, by close linking up of his area surgical work with that of an institution and based upon it frequent reciprocal visits and interchange of medical staff being an important part of the scheme.

In this way the conception of pulmonary and non-pulmonary tuberculosis is one and the same disease, of which only the local manifestations vary would be preserved, and the present tendency to divorce tuberculosis of bones and joints from general tuberculosis and attach it as a mere appendage to orthopaedics would be checked, a tendency which I am convinced is not in the best interests of the patient.

Tuberculosis whatever its site is the same pathological process diagnosed by the same procedure and treated on the same principles and the utilization of methods of treatment similar to those of orthopaedics should not blind us to the fact that the essential element in the successful management of each is a sound knowledge of the disease as a whole—knowledge fortified by manual dexterity and reinforced when required, by the operative skill and expert knowledge of the general or orthopaedic surgeon.

In dealing ever with non-pulmonary tuberculosis the practitioner in charge should be first and foremost a physician armed with a surgeon's technique and not a surgeon doomed to practice medicine.

There would be very definite advantages if this unification or closer interrelation could be carried out. For example, some much needed precision would be added to our diagnostic criteria, especially in tuberculosis of glands. Our recommendations for treatment would be based on fact rather than on prophecy. Our results although not so flattering, would make us realize that our former failures should have suggested the possibility of reconsidering our diagnoses before we preened ourselves upon our success.

By refraining from making up our minds (although not necessarily withholding treatment) until reasonable probability of the cause amounted to actual or practical certainty we would obviate in a large proportion of cases the mental trauma we inflict so lightly upon our patients to-day and would avoid the finality of notification with its consequences—those administrative measures which have such serious social and economic results to patients and their dependants.

Let us take, as an instance tuberculous glands. If the tuberculosis officer or his residential colleague became the surgeon officer and cashier, and excised doubtful glands for examination we would clarify our ideas considerably as to the distinction between glands that are tuberculous and glands that are something else although possibly at the cost of losing our touching faith in the numerous therapeutic fads that exist for the treatment of this condition.

We would realize more keenly that although it is broadly true that a tuberculous lesion is the local manifestation of a general infection in cervical adenitis both lesion and infection may be localized accessible and suitable for

eradication, and that eradication is the prerogative of the operating surgeon alone.

It would be for the physician to decide whether the enlarged glands were tuberculous by a rigorous process of exclusion by removing every contributory cause, by, if need save direct examination it would be for him to decide whether the disease was localized by careful clinical examination especially of the chest by determining possibly the type of bacillus present by radiography of the hilus, and, in doubtful cases even by prolonged observation of the effects of hygienic measures upon the general condition and weight curve of the patient.

When radical measure had been decided upon, he would choose his surgeon with discrimination bearing in mind that this operation is difficult, tedious, and unpopular, that too often those who can won't, and those who will can't, that sometime more vigour than care more trauma than gentleness, distinguishes the technique with the undesirable effect of increasing the risks, always present, of general dissemination of direct spread with its complication and of nerve injury with its consequences. He would also see that the cause—the primary source of infection in the tonsils and adenoids or teeth—was removed as well as the consequence—the diseased glands themselves.

If the surgeon in his turn remembered his medicine he would not operate in unsuitable cases—the cases in which a pulmonary lesion co-exists in which the suprarenal gland or villous glands are involved or in which the disease, although still possibly confined to the lymphatic system, has passed beyond the reach of his knife. He could however, teach the physician the value of his methods of immobilization in the treatment of pulmonary disease, for example, by the use of a plaster bed in the treatment of abdominal adenitis by similar means and in the treatment of glands of the neck by such methods as a plaster collar. He could point out the object lessons that may be learnt from the benign course run by pulmonary tuberculosis when associated with tubercle elsewhere due partly at any rate to the more complete rest secured by surgical methods.

In "orthopaedic" tuberculosis it must be admitted that the balance of advantage resulting from a closer association of the medical and surgical sides would be with the tuberculosis officer. He would be reassured by soon finding out that in early cases there is as much difficulty on the surgical side in deciding whether there is definite evidence of tuberculosis or not and if disease is present in stating whether it is active and requires treatment as there is on the medical side while the choice and duration of treatment and the differential diagnosis may be even more baffling although unfortunately the price of error which the patient pays is frequently heavier in loss of time money and opportunities.

Few problems in medicine require nicer judgement or greater patience than to decide in bone and joint cases when the disease is quiescent and treatment can be altered, or when the disease is arrested and treatment can be discontinued.

In early lung involvement the issue is usually clear—namely the presence or absence of tuberculosis in non-pulmonary tuberculosis the issue is complicated by the necessity in addition of differentiating between tuberculosis and a number of conditions which may closely simulate it—conditions which may require treatment, but have a very different prognostic import.

Tuberculosis officers may therefore, take heart of grace when they are puzzled in arriving at a complete diagnosis with the limited facilities they have at hand. Experts themselves with all the diagnostic aids of a well equipped institution at their disposal are sometimes foiled and have to play for safety either by assuming the presence of the graver disease or by containing themselves with an approximate diagnosis which only time and observation will more accurately define.

On most occasions, therefore tuberculosis officers should content themselves with a provisional diagnosis and act upon it. Until tuberculosis officers are physicians and surgeons too we must follow the advice so admirably emphasized by Mr. Girdlestone—namely, the sufficiency of a preliminary provisional, or approximate diagnosis, provided it is followed immediately by such action as

attendance at a clinic or admission to hospital, where the differential diagnosis can be elucidated without detriment to the patient, and where treatment can be initiated without loss of time.<sup>2</sup>

In this respect the interrelation that exists at present between the physician and tuberculosis surgeons is comparable to that which exists between the general physician and general practitioner, and for the same reason—not necessarily because the one has a specialist knowledge compared with the other (it is hoped that that reproach will soon be removed), but because the surgeon has at his command institutional and other facilities which are essential for prompt diagnosis and treatment.

The benefit of closer co-operation or unification would not, however, be entirely on the physician's side. The surgeon would begin to pay more than lip homage to the truth that tuberculosis is one and indivisible, and that bone and joint disease is a secondary manifestation to primary infection elsewhere. He would act more frequently upon the fact that while coincident clinical tuberculosis of these structures is admittedly uncommon, evidence of bony involvement or of pulmonary disease can be found oftener than is generally realized, and that to treat the diseased joint only is not the whole, and may not even be the most important part, of the treatment, which should be threefold—directed towards the patient, the occult primary lesion, as well as to the obvious secondary manifestation.

It would be more generally realized that in associated pulmonary and non-pulmonary disease premature success in arresting the local lesion (especially if the former is the primary manifestation) may over-activate or reactivate the trouble in the lung.<sup>3</sup> It would be remembered also that, while the development of secondary deformities is a reproach, evasion in attempts at preventing or correcting the primary deformity may not be too high a price to pay for life.

The surgeon's association with the tuberculosis officer would enable him to realize more vividly the economic repercussion in adult patients of his occasionally too conservative methods in some lesions of the lower limb. He would also realize that after-care in tuberculosis, as opposed to orthopaedics, is more than a medical problem, and connotes much more than the correct use of appliances, that failure is not necessarily due to indifference or carelessness, but to those social and economic disabilities that exert such a profound effect upon the prognosis of tuberculosis in any form.

In closing, may I express the hope that my colleagues in the tuberculosis service will realize before it is too late the need for proving themselves equal to the new and fascinating demands that are being made upon their adaptability, intelligence, and clinical knowledge.

#### DISCUSSION

Professor J FRASER (Edinburgh) agreed as to the necessity and value of co-operation. The present-day principles underlying the successful treatment of non-pulmonary tuberculosis could be summed up as (1) removing the local infection if reasonably possible, (2) stimulating the general resistance of the patient, (3) putting the affected part at rest, (4) attacking directly the infecting organism—by tuberculin, serums and drugs, and (5) treating the various symptomatic disturbances. So far as treatment directed towards cure of infection was concerned, drugs had been disappointing, a specific chemo-therapeutic agent had still to be discovered. Hoping in the future co-operation of the pharmacologist and the clinician, the laboratory and the ward. He had not been able to obtain a reasoned opinion on the real value of tuberculin in its therapeutics, its method of administration, and the technique of its dosage. He did not doubt that this treatment had some value. He was more convinced than ever of the correctness of surgical intervention in the presence of certain definite indications, such as tuberculous disease of some groups of cervical glands. This infection remained for some time a local disease, infected from a local point of lymphatic absorption.

There was at present no sure method of arresting the disease by conservative and therapeutic means, and the results of surgical treatment justified this procedure. Rest was the basis of local treatment, and it should be as complete as possible, it encouraged fibrosis, which was nature's method of arresting the tuberculous focus. In the ideal result was to be attained there should be no sudden resumption of function, there the physician and surgeon could usefully co-operate in the constant vigilance of apparently cured cases. He was very sceptical of the success of any scheme for the training of a special type of individual—a physician with a surgeon's training—and preferred the collaboration of a physician interested in tuberculosis as a general disease with local manifestations, and a good general surgeon with orthopaedics as his hobby.

Mr G R GIRDLESTONE (Oxford) thought that in the case of badly deformed patients the criticism should be directed against failure in orthopaedic technique during the period of active disease rather than against any excessive conservatism. The division of potential cripples into tuberculous and non-tuberculous would prove to be neither economical nor efficient. The treatment of tuberculous bones was not merely an appendage to orthopaedics. A recent census of the Wingfield Orthopaedic Hospital had shown that of the 134 cripples and potential cripples well over two-thirds were tuberculous. Adolescents and adults presented a much more serious problem than children. To deal with adult tuberculosis was difficult, the best operative facilities and a highly trained surgical team were necessary.

## PROBLEMS OF MALARIA PROPHYLAXIS.

### CONCLUSIONS OF THE MALARIA COMMISSION OF THE LEAGUE OF NATIONS

BY

LIEUT COLONEL S P JAMES, M D, I M S (RET),  
Adviser on Tropical Diseases, Ministry of Health, London

THE thirtieth anniversary of the discovery by Sir Ronald Ross that anopheline mosquitoes are hosts and carriers of the malaria parasite falls within a few days of this year's meeting of the British Medical Association. Since the discovery, many antimalarial campaigns based on its teaching have been undertaken in various parts of the world. It seems appropriate, in a discussion on the prophylaxis of malaria at this meeting of the Tropical Section of the Association, to consider what practical conclusions can be drawn from the results of those campaigns, and what general recommendations or suggestions can be made as to the antimalarial measures which appear, from the experience gained, to be most suitable in different circumstances and conditions at the present time.

It happens that, as *rapporteur* to the Malaria Commission of the League of Nations, I have recently assisted in drawing up the Commission's provisional conclusions on that subject, and perhaps those conclusions may serve as a basis for the present discussion. The Commission, as every one knows, is an international group of expert malaria-ologists and public health officers who were appointed by the Health Committee of the League of Nations in May, 1923, with the primary object of pooling experience in order to establish what antimalarial measures are most appropriate in certain European countries which have little money for the purpose, either because of general want of resources or for the reason that the funds available must be used in accordance with the relative importance of malaria as a cause of sickness and death in comparison with the importance of other diseases and conditions which affect the public health. This financial limitation adds greatly to the interest of the subject, but also makes the task of giving advice more difficult. The Commission has studied the problem in various ways, but chiefly by undertaking collective study

\* The opening paper of a discussion in the Section of Tropical Diseases at the Annual Meeting of the British Medical Association, Edinburgh, 1927. Dr Andrew Balfour, President of the Section, was in the chair.

tours in malarious regions of Europe and neighbouring countries, where an endeavour has been made for some years to deal with malaria in the light of existing knowledge and experience. During the journeys observations made by individual members of the Commission are examined by other members and the results are discussed in full session by malariologists belonging to very varied schools of antimalarial practice and opinion. In this way individual views become modified and the Commission as a whole endeavours to arrive at an impartial judgment regarding what may be the wisest course to pursue in different circumstances when due consideration is given to administrative and social and economic as well as to technical difficulties. In most instances of course the final view of the Commission is a whole represents a compromise between opposing tendencies—a compromise which may be called the average opinion. It is believed that these mutual discussions are the first session on which the collective thought of malariologists of different countries and different schools of teaching and practice, has been brought to bear on local problems of malaria prophylaxis studied on the spot.

With this preliminary explanation I propose now to bring to your notice some of the conclusions arrived at. In the time at my disposal I must limit myself to those which seem to be of not importance and I can only summarize very briefly the information and reasons on which the conclusions are based. For further details I would ask those who will take part in the discussion to consult the printed report which has been distributed.

1 One of the first and most important conclusions stated by the Commission is that at the present time in the vast majority of the numerous regions where malaria prevails, antimalarial measure should be limited to an endeavour to reduce the severity and so far as may be possible by the same measures the incidence of the disease. They are of opinion that measures designed to accomplish more than that (and particularly measures aiming at "eradication") are not a wise proposition and can be justified only in very exceptional circumstances. As regards this conclusion it is realized of course, that the limited aim is not entirely satisfactory—first as Professor Gosio has written,

No victory is real that does not overcome the endemicity of the disease and suppress its sources, failing this we can only claim to have scotched an ever-threatening enemy whose reawakening is an ever-present possibility." This is true but in the thousand and one small towns and villages of every affected country the "scotching of the enemy" is all that can be hoped for, and in the present state of knowledge it is all that should be aimed at. The Commission points out that those who are dissatisfied with this limited aim may derive comfort from the knowledge that it is all that has been accomplished even in countries like Finland, Holland and Denmark which geographically, financially and in every other respect are much more favourably situated for obtaining success in the eradication of malaria than is any other affected country.

2 A second conclusion of general interest is that it is not always necessary to deal with malaria by a method arising directly out of the knowledge that the disease is transmitted by mosquitoes. In this connection the Commission cites various regions and localities in which in the past malaria was robbed of its importance as a cause of sickness and death without any knowledge of the etiology of the disease and without any reduction of anophelids having occurred as well as various localities in which the same result is being brought about to-day. The Commission observes that since the advent of the knowledge that malaria is transmitted by mosquitoes there has been a tendency to forget that there are many methods of dealing with the disease and that some of them are effective even without an attempt being made to reduce mosquitoes. Therefore their view of opinion that in certain circumstances it is very desirable for antimalarial workers to throw off the trammels resulting from the general belief that because

mosquitos carry malaria their elimination should be the chief object of concern and expenditure.

3 A result of the Commission's inquiries which is closely related to the conclusion just stated is the recognition that there is not yet any single method of malaria control which can be described as being superior to all others and therefore to be adopted in every country. There are, as has already been said, a number of methods of control, and some of them are constantly being improved. Each or any of them may, either wholly or in part render valuable service in a country if it is a method well suited to the local conditions. This suitability or adaptability to local conditions is one of the most important matters to be considered in a choice of methods, and it is essential to the success of the method chosen. Malaria control is a local problem to a much greater degree than is the case with the control of other infectious diseases. Therefore in every country and very largely in every area there must be preliminary examination to ascertain the local conditions before deciding what method of malaria control is best adapted to them.

4 Omitting the Commission's suggestions for ascertaining the amount and character of malaria in the locality and for ensuring that a continuous record on that subject will be kept I turn now to the actual methods of controlling malaria which the Commission consider it desirable to recommend. First I must say a word on the second question whether it is better to utilize several of the known antimalarial methods at the same time, or to concentrate all available effort on one carefully elected method. This is a specific question which was put to the Commission by the public health authorities of several countries visited. The answer given was that in the opinion of the Commission it is better to limit the action taken to one or two selected methods, which can then be brought to a high degree of perfection. If, after a fair trial, these one or two measures are found to be insufficient to rob the disease of its practical importance from the public health point of view further methods can be systematically added until the desired end is attained.

5 As regards the particular methods of malaria control to be adopted in any country or area the Commission considers that there should be considerable freedom of choice. It deprecates the adoption of measures in a country on the ground that they have been successful in another, where perhaps circumstances and conditions are quite different. Each country and to a more limited extent each locality must work out its own salvation. In this matter, and the suggestion is made that countries and localities should do so in greater degree than has hitherto been the case. On this point the Commission states that in some of the countries which they visited there was evidence of an endeavour to follow too slavishly the antimalarial policy adopted in some other countries without ascertaining its suitability to the local circumstances and conditions and in some instances without interpreting correctly its purpose and without giving full weight to the considerations which determined its adoption. As an example they note that in the world generally, there is a widespread misapprehension regarding Italian antimalarial methods and that, in some countries money, energy and time have been misapplied in the false belief that the Italian example was being followed.

6 It is usual to classify antimalarial measures as direct and indirect. The Commission adopts that classification but defines the terms more strictly than is usual. In the Commission's view there are only two direct antimalarial measures—namely killing the malarial parasite in man, and killing the malarial parasite in infected mosquitoes. In comparison with these two measures, anything else that can be done to control malaria is necessarily indirect. For example no one who has made a particular study of antimalarial campaigns can doubt that general antimalarial measures in the field as usually carried out in practice, are an indirect method of trying to deal with human malaria—that this line of action is concerned with something which is remote from the particular knowledge of the etiology and epidemiology of malaria which we are fortunate enough to possess to-day.

<sup>1</sup> *Principes et méthodes de lutte antipaludique en Europe*. Deuxième rapport fait au Conseil de la Conférence du Paludisme. Publié par le L. I. de l'Union internationale pour l'étude du Paludisme, 1925.

<sup>2</sup> *International Journal of Public Health*, vol. 1, No. 2, September 1926, pages 173.

7 Adopting this restricted definition of direct and indirect means of controlling malaria, the Commission suggests that in every malarious locality certain direct methods, which they term "primary measures" and which are concerned with malaria-infected individuals and the interior of the houses in which they live, are indispensable. As regards measures relating to malaria-infected individuals, the Commission considers that, whatever else it may be possible to do in malarious localities, the first and most important thing to do is to arrange for the treatment of cases of the disease. In rural areas and localities under primitive conditions the State must make these arrangements, according to the means available, but at least an efficient arrangement for the gratuitous supply and effective distribution of quinine is indispensable. The Commission considers that in organized communities satisfactory diagnosis as well as treatment should be arranged for, and suggests that, wherever possible, the services of private medical practitioners already established in the locality should be utilized and paid for by the State for this work.

8 The Commission recognizes that no useful purpose would be served by magnifying unduly the results that may be obtained by those arrangements for ensuring early discovery and effective treatment of cases and carriers. They have ascertained that, in the countries which they visited, nothing is more striking than the mild character of the manifestations of malaria in a locality where there are practising medical men who are fully equipped as to the diagnosis and treatment of the disease, as compared with the severe and often fatal manifestations in a similar locality which is without that expert medical aid, but they realize also that the good results are more apparent in the reduction of severity and mortality than in the reduction of incidence. This is not surprising in view of the knowledge that quinine is not an effective prophylactic for new infections or relapses, and in view of the difficulty of attaining the "minimal effective standard" in the execution of the measures. Regular inspection of school children and of organized classes of the adult population must be part of the system, and an endeavour must be made to follow up all patients in their homes. The officer who is in charge of the measures will need assistants, especially for house-to-house inquiries. In some countries duly qualified female "health visitors" who have received the necessary training may be usefully employed in this work. In small districts the office can be combined with kindred health duties, such as school nurse, tuberculosis visitor, etc.

9 The other "primary measure" which the Commission recommends is the systematic killing of adult female anopheles mosquitos which can be found in the interior of dwelling-houses. It would take too long to describe in this paper the epidemiological and experimental grounds on which the Commission has arrived at the conclusion that this measure, if it could be effectively carried out, would have very remarkable results. As to the manner in which it should be done, the Commission considers that, wherever it may be practicable to persuade householders themselves to undertake it, that arrangement is preferable to an organized management by the authorities for killing mosquitos in houses by periodic fumigation or other means. In the Commission's view the measure should be regarded as an important item in the sanitary education of the inhabitants of malarious areas. The Commission thinks that it should be a duty of the medical men and assistants who visit households to explain to the occupants how malaria is contracted and spread, and to demonstrate to them how to find and kill the adult anopheles mosquitos which are present in the house. It should be explained also how to make the house inhospitable to anopheles by removing cobwebs and dirt, clearing out recesses and dark corners, whitewashing, arranging for more light and air, and other simple means suitable to the particular locality and type of dwelling. Female health visitors and health nurses, who have been properly instructed and trained, can do a great deal of good by instructing householders on these matters. The aim should be to teach the inhabitants to have the same dislike and objection to the presence of goaded and sluggish mosquitos in their houses as cultured people already have to the presence of bed-bugs, lice, and

other harmful and disgusting vermin. If this educational propaganda is successful, it may be hoped that in time the killing of anopheles mosquitos in houses will become a routine part of the housewife's daily task, just as much as other more showy, but less useful, items of sweeping, brushing, and cleaning. The measure has the advantage of costing nothing. It is known, from the results of experimental laboratory work, that one infected mosquito can give malaria to as many as thirty persons, therefore it is difficult to prize too highly any person who succeeds in killing even one of these infected insects.

10 As regards these two primary or direct measures, the Commission is well aware that there is nothing particularly new or original about the idea of endeavouring to combat malaria in the houses of the people themselves rather than in the general environment. They realize also that it is often a difficult matter to get into the houses of the people, to examine all the occupants, to treat those who are found to be infected, and to teach them to catch and kill the mosquitos which may be hidden in inaccessible places. But no novel road or short cut to the prevention of malaria has yet been found. Therefore, in the opinion of the Commission, it is necessary for the present to continue to endeavour to combat the disease itself at its sources in the human and insect hosts.

11 The Commission has carefully considered in what circumstances any other measures than those dealt with should be recommended, and what those measures should be. On this subject reference is made in the first place to the problem of what should be done in regions where the conditions in which the people live and work are so primitive, and their economic position and social status, and culture are so poor, that it is not possible in practice to apply direct antimalarial measures in a manner which enables them to be brought to the "minimal effective standard." Except the free distribution of quinine, no effective antimalarial measure can be applied in these regions until the land has been brought into such a condition that it is worth the while of the inhabitants to settle permanently upon it, and until those permanent settlers have reached a fair standard of housing and living. Nothing is more favourable to a high incidence and severity of malaria than frequent movements of a population hither and thither in search of a better living, and very few things have a greater effect in reducing malaria than the stability of the population which comes when a place where the conditions of life are tolerable is found. Agricultural reclamation of the land, so that people may be settled permanently upon it with a fair prospect of gaining a livelihood, and perhaps a decent house and moderate comfort, is therefore a measure which tends indirectly to produce a great reduction of malaria. In general, the better the agricultural reclamation is carried out from the point of view of increasing its productivity, the quicker will malaria seem to disappear as an important cause of sickness and death—provided always, of course, that the people themselves share in the improved prosperity by being able to adopt a higher standard of housing and living. It is hardly necessary to say that, when reclaimed land is worked by hired labourers who receive only a small daily or weekly wage and live a life of great hardship in temporary huts and hovels, there is no improvement of malaria among them. Indeed, in the tropics (and even in some parts of Europe) highly cultivated areas where these conditions obtain continue to be among the most malarious in the world. This indicates that the actual measures necessary for agricultural reclamation or improvement of the soil (drainage, etc.) are not the factors which cause the health of the people to improve, but that the good result is due to the better conditions of living and housing which the increased productivity of the soil enables the people to obtain. In this connection the Commission notes that the changed conditions of life just referred to, and the subsequent reduction of malarial incidence and severity, have often been brought about in the absence of any measures intentionally based on modern knowledge of the etiology and epidemiology of malaria, and they illustrate this truth by describing a small scheme of "sanitation without antilarval or other intimosquito methods" which was demonstrated to them during their tour in Sicily. The

place is now an example of 'anophelism without malaria' for the one and other reasons the conclusion to which the Commission has come is that of all indirect methods of reducing malaria most importance must be attached to general schemes which aim at improving the economic and social conditions of the people and their general well being and standard of life.

12 The Commission has ascertained that almost everywhere in the countries which they visited terms like "bonification," "reclamation," etc. are misunderstood and misinterpreted except in the particular countries where the term originated. They find also that in some countries the false belief still prevails that the actual measures which are necessary for making land more suitable for cultivation and more fertile are the means by which the reduction of malaria is brought about. In particular the drainage which is necessary for agricultural land reclamation is often credited with being the chief agent concerned. It is assumed that the drainage acts by reducing the breeding places of anophelid mosquitoes. In support of this belief it is often said that even the ancient Greeks knew that drainage reduces malaria and that this antimalarial action of drainage is explained when the role of the mosquito was discovered. One result of the belief is that some countries have adopted drainage on a large scale as their first line of attack against malaria. The Commission does not desire to limit the output of public works of proved utility but having regard to the financial aspect of its mandate they are equally unwilling that countries should continue to believe that the kind of drainage which is necessary for agricultural reclamation of the soil is an important antimosquito measure. For it is now known unquestionably that the open ditches and canals by which swamps and marshy areas are drained for agricultural purposes are often more prolific breeding places of anophelid mosquitoes than were the original swamps themselves. The Italians are well aware of this. They do not regard their "large bonifications" as an antimosquito measure and they know that such a bonification may increase the abundance of anophelid in the area reclaimed. But they know also that in an area where bonification has been completed and where, in consequence, the inhabitants settle permanently in better houses and in all the other circumstances of a moderately good standard of life malaria tends more or less quickly to lose its importance as a cause of sickness and death. This good result more than compensates for an increase in the abundance of anophelid in the general environment. Thus it appears that the measures themselves are only a means to a definite end which is to be pursued despite the knowledge that some of the measures may be of a kind which actually favours the incidence and spread of malaria. Therefore what we learn from the Italian example (and equally from the older and more extensive Dutch example) is that we must not take credit of the actual bonification measures (such as drainage) separately, and utilize it as a single antimalarial measure in another country. If "bonification" is the antimalarial measure which we desire to employ, it must be understood to mean a many-sided process. Our scheme for "bonification" must be comprehensive, it must include particularly the arrangements for settling the people permanently, for raising their standard of life for better housing, better education and general welfare for making scattered homesteads of recess by good roads and canals, for better medical attendance and in general for all the social and public health improvements which are an integral part of a complete bonification scheme in Holland, Italy, and other countries where such schemes have been successful. As I have already mentioned, the essential importance of these items in the scheme is brought home to us by instances in which when the inhabitants of reclaimed and highly cultivated land are not permitted themselves to reap the advantages of the increased productiveness of the soil no improvement in malarial results. Obviously, therefore the sphere of the public health officer and the malariologist in connection with schemes of agricultural land reclamation consists particularly, not in trying to enforce antimalarial measure during the progress and after the completion of the work but in seeing that the agricultural improvement has been

unaccompanied and followed by an equal improvement in the conditions of life of all the people who inhabit the reclaimed area. This change in the conditions of life of the inhabitants is the most important antimalarial factor in bonification schemes.

13 The Commission deals in separate chapters of the report with various other problems of malaria prophylaxis particularly with the organization necessary for the work and with different antimalarial and antimosquito methods—such as quinine treatment and prophylaxis, larvicides, the applicability of antimalarial measure housing, an antimalarial measure, and propaganda. From lack of time I cannot refer to these subjects in the present paper.

14 But there remains a subject which I must not omit to mention. For various reasons which are given in the report, the Commission is unanimously of opinion that the scientific study of malaria must be continuously pursued in the laboratory and the field. They consider that the best prospect of discovering a method of dealing with malaria which can be applied in affected localities with the small amount of money and means that can usually be provided lies in renewed activity in the study of the disease in all its aspects. Therefore they suggest that each Government which has not already done so should establish a small central permanent organization of selected workers who would devote their whole time to malaria research. In this connection they suggest (a) the establishment in one or two malarious areas of each country of an "observational station" where certain routine epidemiological inquiries should be made at regular short intervals for several years, (b) the establishment in each country where malaria is used therapeutically of a laboratory for the cultivation of a pure strain of malaria in mosquitoes to be used, under expert supervision for the purposes of the treatment. The establishment of such a laboratory in a properly organized hospital automatically provides an opportunity of studying the clinical and parasitological features of malaria contracted in the natural way as well as the circumstances governing the infection of anophelid and the persistence of the infective virus in those insects. It also enables a satisfactory study to be made of the action of quinine and other drugs which are used for the treatment of malaria. Examples of each of these institutions are described in the report as well as an example of a station for "experimental malaria control."

#### DISCUSSION

Lieut Colonel F. D. W. HACKETT with the aid of lantern slides outlined the problem of malaria prophylaxis which emerged from his study of certain cases of intentionally induced malaria. He divided his cases as regards susceptibility into (1) refractory and (2) ordinarily susceptible. The difference was very clearly observable but in this series there were none which could be classed as very susceptible. He recalled that James had ascribed resistance to infection to some property of the blood or tissues of the recipient and not to an insufficient dose of sporozoites and he discussed the views of Christophers as to immunity against malaria expressing the opinion that some test which would differentiate good and bad infectors of mosquitoes would be of service for prophylaxis. In his cases the period of latency after infection varied from six to twenty days. Sexual forms of the parasite did not appear until six or seven days after the disease declared itself so that allowing three days which James held to be necessary before gametocytes could infect mosquitoes a patient in a primary attack would not be capable of infecting mosquito until about ten days further had elapsed. Such intentional infections as those described afforded opportunities for study of the parasitological power of drug.

Dr F. W. HACKETT (Rome) described the use of Paris green in the antimalarial measures undertaken by the International Health Board in Italy.

Dr DRPOMAY (Prague) gave an outline of the conditions of occurrence of malaria and the methods used against the disease in Czechoslovakia.

Prof. Dr E. MATTI (Hamburg) feared that the report of the Malaria Commission would be interpreted by

Governments as meaning that by supplying free quinine they could discharge their whole duty regarding malaria. He leaned towards the preventive methods described by Dr Hackett, but he agreed with Colonel James that there was perhaps too great a tendency to adopt mechanically for every country a measure which had anywhere produced good results. For malaria prevention there was no fixed rule, each district required individual consideration. At a place he visited near Astikhin prophylactic quinine was the only measure applicable to local circumstances. Angola was nearly abandoned as the Turkish capital on account of malaria, quinine alone was ineffective, but when this was coupled with well considered drainage the disease was controlled, and anopheles became rare. In Antolia it was the experience of local doctors that apparent resistance to quinine often disappeared when an malarial infection had been eradicated. In his view the cases of so-called spring malaria were nearly always relapses of autumn infections. In Turkey he had acted on this belief as regards his personal prophylactic measures, omitting all precautions up to the end of May even in districts where malaria was endemic, and he had no reason to regret his action.

Dr P H MASON-BARR (London) gave his experience with plasmochin and its compound with quinine in the treatment of malaria. He considered that this new drug, from its action on the gametocytes of tertian and subtertian parasites, would have considerable bearing on the prophylaxis of malaria in the future. All who had used it were agreed as to the phenomenal rapidity of its action upon the crescents of subtertian malaria, which disappeared from the circulation within three days after the exhibition of 0.24 gram of plasmochin. He quoted a striking illustrative case in which the compound was successfully employed after full doses of quinine had proved unavailing, and in which disintegration of the gametocytes was observed microscopically. The drug was well tolerated, and if it were possible to treat a malaria-stricken population daily with small doses, the transmission of infection through the anopheles would soon cease from destruction in the blood stream of the gametocytes. Under the present system of quinine prophylaxis the formation of gametocytes in peripheral blood was rather encouraged than the reverse.

Colonel S P JAMES briefly replied to the discussion.

## ASTHMA AND TUBERCULOSIS IN RELATION TO "CLIMATE ALLERGENS"

BY

W STORM VAN LEEUWEN,

DIRECTOR OF THE PHARMACOTHERAPEUTICAL INSTITUTE OF THE UNIVERSITY OF LEIDEN, HOLLAND

We began about 1919 to investigate the action of various allergens on asthmatics, and found that only about 15 per cent of our cases could be classified as super-sensitive to the four groups of allergens known at that time—namely, pollens of various grasses and flowers, epidermal products, foodstuffs, and bacterial vaccines. We had, however, also noted those asthmatics who could not be classed under one of the four headings mentioned, but had yet to be considered super-sensitive, although we were unable to identify the causative allergens. Among other things we found that more than 90 per cent of asthmatics give a positive skin reaction to an extract of dandruff of human skin, whereas normal persons only react to such an extract in exceptional cases, proving that the skin at least of these patients is super-sensitive.† Thus about 80 per cent of our asthmatics suffered from some form of allergy, but the causative agent of their attacks was unknown.

In our endeavours to find the cause of the attacks in these 80 per cent we utilized the known fact that the environment of the asthmatic patient is, as a rule, of primary importance in determining the intensity and frequency of his attacks. It is known that most asthmatics are free from attacks at high altitudes. Turban and Spengler, who have published statistics for Davos (about 5,000 feet), found that 68 per cent of all asthmatics going to Davos become free from attacks within two or three days, that 25 per cent improve considerably within two or three weeks, and that only 7 per cent remain unimproved. It is also known that residence at the seaside or a sea voyage often improves the condition of asthmatics. This can be observed also in a flat country like Holland, where the health of asthmatics varies greatly in different regions. The character of the soil is also of great importance, sandy soil and a low level ground-water offering much better conditions for asthmatics than clay and peat soil and a high level ground-water. Recently these observations have been confirmed completely for Ost Preussen by Tiefensee, working in the clinic of Matthes in Königsberg, who found that from 1,100 asthmatics living in East Prussia, more than 90 per cent had their houses on clay, moor, or peat soil, and only a very small number on sandy soil.

These observations exclude the known factors of climate, barometric pressure, temperature, humidity of the air, etc., as direct causes for the incidence of asthma, and make it clear that the conditions of the soil are of paramount importance. As will be shown later, humidity may play an important part in making a place "bad" for asthmatics, but it does this by facilitating the growth of certain microorganisms which constitute the determining causes of the asthmatic condition in different regions.

Mainly on the basis of such observations we formulated the hypothesis that the difference between various climates is due to certain allergens in the air, the presence of which is dependent on factors of climate, they may be called climate allergens. These climate allergens must be considered as the principal causes of asthma in all flat countries with a high humidity and a moist soil.

In my monograph on allergic diseases<sup>1</sup> I fully described the results of experiments made to prove the validity of this hypothesis. Among other things it was shown that outside air in a place known as very bad for asthma (Rotterdam) contains water-soluble colloidal substances, which on injection into sensitive persons induce attacks of asthma, and that dust from the floors of private houses gathered in regions where asthma is very frequent contains many more allergens than dust from places which are good for asthma. In Switzerland there is a gradual diminution in the allergen content of house dust corresponding to the height of the place.

A number of allergens which may be considered representatives of groups of climate allergens have been determined. The first examples were found by us as the result of reading a paper by Ancona, who observed an epidemic of asthma in an Italian village, the cause of which was traced to a parasite occurring in grain (*Pedicularis ventricosis*) which formed allergens, to which most of the people who frequently handled this grain became sensitive. We then found that other insects—that is, the common mites which so frequently occur in grain, hay, and straw and picking material—form allergens which may be the exciting cause of asthma in about 20 per cent of our cases. Later we found that common moulds, like *Aspergillus fumigatus*, and other aspergilli, penicillium, mucor, etc.—moulds that are abundant in moist and damp houses—form allergens to which more than 50 per cent of our asthmatics are sensitive.

Since these allergens formed by moulds are to be considered as typical representatives of a group of allergens which is certainly most important for the entire problem of allergy, we will have to study their properties in detail.

### Properties of Mould Allergens

1 Mould allergens are soluble in water and are of colloidal nature, they are not destroyed by heating to 120° C, nor by acid, alkali, or formaldehyde. They are

\* This article is a synopsis of a series of three advanced lectures given at the London University in February, 1927.

† The results have been confirmed by Prof. Dr Rost in Freiburg (Germany).

not soluble in ether or chloroform and are probably not proteins or lipids. They are known to neutralize acid or alkaline and do not act as nephelotogens in guinea pigs or rabbits so that it has not been previously possible to sensitize animals with these allergens.

2 *Skin Reactions on Human Beings*—In about 50 per cent of our asthmatics these mould allergens give positive skin reactions after subcutaneous injection, whereas normal persons are as a rule negative. The reactions are sometimes very intense so that the area for some at the site of injection is swollen, red, and tender, and so remains for two days.

3 *Effect of Subcutaneous Injections on Human Beings*—Subcutaneous injections in normal persons give no reaction. Sensitive people however may react in a peculiar way. Small doses, about 1 in 1,000,000 or less of our standard extracts, often have a decided therapeutic effect in that it repeated at short intervals they serve to desensitize a patient sometimes to a considerable degree. Slightly higher doses—that is 1 in 100,000 or the standard extracts—may cause symptoms of vasomotor rhinitis, headache, rise in temperature, and general malaise. In very sensitive people the 1 in 1,000,000 dilution or even 1 in 10,000,000 dilution may have the same effect. Higher doses or the same dose in a sensitive patient may produce violent attacks of asthma and even be dangerous. The symptoms following the injections of mould extract last two or three days and may be stopped by the injection of a solution of sulphur in oil.

4 We have been able to prove that the serum of patients sensitive to moulds contains substances which may transfer this sensitivity locally to the skin of normal persons. This serum also contains substances which may inhibit the action of the allergens in sensitive persons. Both kinds of substances are strictly specific. The presence of a "transfer substance" is shown by the experiment of Praeger and Kustner. If 0.1 c.c.m. of serum from a patient hypersensitive to a certain mould extract is injected into the skin of the flexor aspect of the left arm and next day 0.1 c.c.m. of mould extract is injected in the same place and 0.1 c.c.m. of the same extract as a control in the right arm the injection in the left arm will produce a large urticarial wheal, but the result of the injection in the right will be negative. This experiment proves beyond doubt the importance of moulds as a factor in allergic disease.

The presence of specific anti-allergens may also easily be shown. If 0.1 c.c.m. of a solution containing a mould extract diluted 1 in 10 with physiological saline is injected intracutaneously on the flexor aspect of the left forearm of a patient hypersensitive to moulds, and in a corresponding place on the right arm a 1 in 10 solution of the same allergen diluted with the patient's own blood is injected, the reaction on the left arm will be positive and on the right arm negative.

Whether these anti-allergens are identical with the "transfer substances" is not certain. The experiment described proves that the moulds investigated form allergens which may induce symptoms of illness in persons hypersensitive to them, and the conclusion is strengthened by the fact that all the moulds used have been cultivated from material occurring in the close vicinity of asthmatics. We have frequently found *Aspergillus fumigatus* growing readily in Lapok, which is used for stuffing mattresses in my country, moulds can be cultivated from house dust, from grain, and from human dandruff—in fact from the most various sources, but all accessible to asthmatic patients. Although we have only investigated the allergic properties of about sixteen moulds, many others may act in the same way as well as some micro-organisms such as bacteria and yeasts. Other climate allergens perhaps more important than these, may yet be found, but so far as we can see at present the relation between mould allergens and allergic diseases is the same in all low-lying countries. Those investigating this subject must not forget that the kind of micro-organisms producing climate allergens may be different in different countries.

So far we have produced evidence for the theory which ascribes the beneficial influence of high mountain climates

for all types to the absence of climate allergens in the air. The final proof can be reached in another way. If the beneficial influence of residence in high altitudes is due to absence of climate allergens, it should be possible to obtain the same improvement in Holland or any other low-lying country provided that conditions could be realized which in respect to the air were identical with those in Switzerland. With the help of W. Linthoven, jun., we have succeeded in constructing an apparatus for investigating this. As this apparatus is installed in a special clinic for allergic diseases, and forms the basis of our work during the last three years, it must be described in some detail.

### The Clinic for Allergic Disease

The clinic is established in two private houses rented for the purpose. The houses are rather badly built, damp, and situated on clay soil in a humid region near a canal. These are favourable experimental conditions since we wish to demonstrate that even in houses otherwise bad for asthmatics it is possible by proper technical arrangements to make them suitable for these patients.

In several rooms of these houses small chambers have been built of cement, a kind of asbestos, and a material on which bacteria or mould cannot grow. The chambers contain an iron bed, an iron chair, and a small iron cupboard. Mattresses, pillows, and other bedding are new and sterilized before use; they are also regularly sterilized every month or six weeks so that the possibility of micro-organisms growing in them and producing allergens is extremely small. Before going to bed the patient undresses in the room but outside the chamber enters and shuts the door of the chamber and stays in it during the whole night. During the first days of the residence in the clinic the patients often stay in the chamber during the daytime also. They are not allowed to take extra pillows, food, or any material which may contain allergens into the chamber. All the chambers in the clinic are ventilated by a large exhaust fan which draws air from the top of an iron tube fixed alongside an iron tower 100 feet high.

The system described is the simplest and for most of our patients it is sufficient. Nevertheless the air with which the chambers are ventilated will contain a certain amount of dust and a certain amount of climatic allergens. Hence, in order to obtain conditions more nearly identical with those in high altitudes the air must be purified—a problem presenting considerable difficulties. So far we have tried three different methods, but only one could be put on an efficient economical basis, that is the air is purified by passage through a refrigerator.

In the clinic for allergic diseases in Leiden there is a refrigerator with a capacity of 6,000 calories an hour and a cooling surface of 120 square feet sufficient to bring the dewpoint of the outside air from 15° C. to 6° C., or from 10° C. to 1° C., or from 5° C. to -5° C. in about 200 cubic feet of air passing through it per minute. This is sufficient to ventilate three chambers for two persons each. The air cooled in this way is to be drawn by a central heating system before it enters the chambers. As a rule the temperature of the chambers is kept at about 70° F., the relative humidity between 20 and 30 per cent. We do not yet know to what extent the dryness of the air influences patients beneficially, but if dryness is an important factor for their conditions in the clinic compare favourably with those at high altitude sanatoriums. It is true that during the winter the relative humidity in a number of places at high altitudes will be lower than 20 per cent, but in spring and part of the summer the figure of most of these places are higher.

We have so far treated about 500 patients in this clinic, and have found that about 75 per cent were completely or almost completely cured within some days about 15 per cent improved materially within some weeks and 10 per cent remained unaltered. In comparing these figures with those published by Turban and Spengler we find almost complete agreement. In our opinion this shows without any doubt that the conception of the influence of climatic allergens on the condition of asthmatics in various climates and at various heights is correct.

### *Application of the Principle of Allergen-free Air Chambers to Other Diseases*

Illnesses dependent on climatic factors are not limited to asthma and the other allergic diseases mentioned. Rheumatism is prevalent in moist and cold climates, and tuberculosis also. Highly interesting and careful investigations by Goidon, which were later confirmed for India by Sir Leonard Rogers, have demonstrated that great differences in the morbidity and mortality of tuberculosis exist between various regions in the same country, often quite near to one another—differences which are ascribed by these authors to the influence of strong rain-bearing winds. Most sufferers from migraine who have visited different places and different countries can tell of places where they are well and places where they always suffer badly. In those regions where the "Föhn" wind prevails its influence is very distinctly recognized by sufferers from migraine and epilepsy. In hot tropical climates there is in the lower regions a peculiar form of disease called "low fever," characterized by malaise and some rise of temperature, this condition is almost immediately cured if the patient moves to the mountains, but it comes back as soon as he returns to lower regions. The cause of this illness is unknown.

We do not suggest that in all these cases factors of climate are to be identified with the presence or absence of climate allergens, but we believe that some of these diseases should be studied from this angle. We ourselves started with tuberculosis, and also had the opportunity of studying five cases of whooping-cough in allergen-proof chambers. Our five patients with whooping-cough had severe attacks of typical coughing every hour or two on the day preceding their admission. They came into the clinic on the sixteenth, tenth, fourteenth, twentieth, and twenty-third day of the illness respectively. They were immediately put in an allergen-proof chamber ventilated with purified air and were not allowed to leave the chamber till their attacks had disappeared completely. As a result not only did the number of attacks of coughing decrease rapidly, but the intensity of the attacks was very much reduced, none of the children had in the clinic any attacks as severe as on the preceding days and nights at home. Although the benefit derived from this treatment is undeniable, we offer no explanation of it. Certainly we do not want to draw the conclusion that whooping-cough is an allergic disease, the subject is a matter for future research.

### *Pulmonary Tuberculosis*

We have elsewhere<sup>1</sup> discussed the reasons which led us to investigate the influence of allergen-free air on tuberculosis. Earlier in our work on moulds we made skin tests with mould extracts in tuberculous cases and found a fairly large number of positive reactions, and this, together with the consideration that high altitudes act beneficially on tuberculosis as well as asthma, suggested taking cases of tuberculosis into our clinic and observing how residence in an allergen-proof chamber would influence them. Although the number of patients so far is limited (16) there is already sufficient evidence that allergen-free air gives about the same results in treatment of tubercle of the lungs as high altitudes. We feel justified in making this statement, in spite of the small number of patients, because the conditions under which our therapeutic experiment was made were such as to exclude most sources of error. All these patients were suffering from severe tuberculosis. Physical and x-ray examination showed characteristic signs of proliferative disease and the sputum contained a great number of tubercle bacilli. Previous to admission they had been treated at home or in hospital in Amsterdam. They had during the preceding months or years spent the greater part of their time in bed, and none had lacked sufficient nourishment. Attention must again be drawn to the fact that the allergen-proof chambers used were built in the rooms of a private house, situated in a very moist and low-lying part, so that the only difference our treatment could make was that the patients were taken from a house in Amsterdam or somewhere else in the country, and brought into another house, certainly not better situated than the one they were in

before, but in which they lived in a small chamber isolated from the rest of the house and ventilated with purified air. Factors of rest, good food, and careful nursing were the same as before, and the patients received no medicines or other treatment, hence, as far as one could see, the only therapeutic measures were fresh air, and in some cases dry air, and protection from climate allergens.

Of the first sixteen cases treated in this way, one was not improved, and curiously enough this was a case which we had considered to be a relatively slight one—a girl of 15 years with tuberculosis of the left apex. One other case, a woman of 26, with a large cavity in the left apex, although gaining considerably in weight and feeling better, did not show much local improvement. A third case also only improved slightly, but all the others improved considerably. After having been in the chambers for one or two days the patients feel better, they breathe more easily, and they cough less. The quantity of sputum may or may not decrease during the first weeks, depending largely upon the presence or absence of a cavity. If no cavity is present the quantity of sputum may decrease quickly, if there are cavities the probability is that sputum will remain abundant and will only diminish very slowly, although in one of our cases with a large cavity (verified by x-ray examination) the patient was free from sputum within a month. The characteristic point, then, is that definite improvement occurs within a few days, and this is precisely what was expected, and is analogous with the improvement in our cases of climate asthma.

Of course, improvements in the patient's condition cannot be expected to show themselves in the physical examination of the chest until after some weeks have elapsed, then we find evidences of exudative processes being replaced by signs of fibrosis. In the cases favourably influenced the temperature settles after three or four weeks, and may remain normal entirely after two or three months. All our patients gained in weight, some of them considerably (15 kg in some months). In two cases the patients went home against advice before they were sufficiently improved, and became worse almost immediately, although all conditions at home, with the sole exception of allergen-proof chamber and purified air, were the same as in the clinic.

Before considering the importance of the results given, I must call attention to the fact that so far I have only spoken of "improvement" and not of "cure" of tuberculosis. In order to appreciate the reason for this it must be remembered that in cases of "asthma" also we do not obtain a cure by keeping the patients in the clinic. Our cases of climate asthma are supersensitive to climate allergens, and consequently they will be subject to attacks in places where these allergens occur, and free from symptoms in places where they are absent. Tuberculous patients suffer from a bacterial infection, and in addition are sensitive to climate allergens. This sensitivity handicaps the patient and forms an additional factor causing the tuberculous process to run a more severe course, it is this additional factor which is absent in our allergen-proof chamber. So the direct influence of this treatment—that is, the degree of improvement—will be mainly dependent upon the degree of sensitization to climate allergens shown by the patient, whereas the final result, including the question of permanent cure, depends on the relation between the violence of the infection and the patient's resistance.

It seems to me that the possibilities suggested by these observations on the influence of climate allergens on tuberculosis are not exhausted here. There is another side of the question which has to be considered. We know that there is a relation between climate and tuberculosis. Why is the mortality and morbidity of tuberculosis high in some regions and low in others? Lack of good food and unfavourable conditions in factories and workshops are important factors, and another is the occurrence of climate allergens in the patients' environment. The knowledge of this factor may be of great help in the treatment of tuberculosis, but it may be of even greater help in prophylaxis. Preventive medicine should take this matter into consideration. If the simple transfer of a patient from one house to another in the same town or region can make all the difference to his

health (as was the case with the patients who came to our allergen proof chambers) it must be realized that one obvious factor in the prevention of tuberculosis is to make the conditions at home similar to those in our clinic.

We feel that for all patients who are free from symptoms of asthma in our clinic, or who, suffering from tuberculosis, are greatly relieved the problem of their health has been reduced for the most part to a problem of technique.

OR

### THE EPIDEMIOLOGY OF POLIOMYELITIS\*

BY

I. M. R. WALSH, M.D., D.Sc., F.R.C.P.

PHYSICIAN IN CHARGE OF THE NEUROLOGICAL DEPARTMENT, UNIVERSITY COLLEGE HOSPITAL, PHYSICIAN TO OUTPATIENTS, THE NAT'IONAL HOSPITAL, QUEEN SQUARE, LONDON

POLIOMYELITIS is an acute specific fever which, in its complete expression presents three distinct clinical and pathological phases. Clinically these are a short lived initial phase of constitutional disturbance, followed by signs of invasion by the virus of the subarachnoid space and finally by signs of involvement of the nervous tissue itself. Each phase has its pathological substratum. In the initial phase the virus obtains lodgement in the liver, spleen and lymphatic structures generally, in all of which lesions are found. The virus then reaches the subarachnoid space and leptomeninges by channels which are not yet fully known and gives rise to a reaction which is manifested by characteristic changes in the cerebrospinal fluid, and finally invading the nervous tissue, it produces there the inflammatory lesions to which the paralysis is due. The intensity of each phase varies as do also the time relations of the first two phases. Further, the infection may die out after the first or the second phase thus giving rise to the so-called abortive cases. When infection dies out after a severe meningeal reaction we speak of a "meningitic" type of the disease.

The initial constitutional phase of poliomyelitis seldom presents sufficiently characteristic symptoms for identification and it may be so mild that the patient continues to go about and thus has ample opportunities of spreading infection since the virus is contained in the nasopharyngeal secretions. Like other infectious diseases it has its own seasonal and age incidence incubation period mode of spread, and susceptibility factor. Since the publication of Wickman's observations<sup>1</sup> it has been generally held that the infection is carried and spread by healthy carriers of the virus and by sufferers from the disease. From the nasopharynx of both groups of individuals a virus has been obtained capable of producing the disease in inoculated monkeys, and Flexner and Amoss<sup>2</sup> concluded that the nasopharyngeal mucosa during the ten days immediately following the initial signs of infection regularly contains the virus.

The two points to which I propose particularly to address myself are the question of non-human carriage of the virus and a view which has recently been advanced to the effect that the sole agent in the spread of poliomyelitis is the healthy human carrier of the virus. Despite the inconclusive results of extensive search for non-human agencies of spread these have not been finally excluded. Recently in a small American outbreak, a strong case has been made out for mill as a possible agent of spread and the whole question has thus been reopened.

An important modification of Wickman's views as to the joint responsibility of healthy carriers and sufferers from poliomyelitis in the spread of the disease has recently been suggested by Collier,<sup>3</sup> who believes that the disease

is spread exclusively by the agency of healthy carriers and that actual sufferers from the disease in any of its phases are non-infective to contact, owing to loss of virulence in the infecting agent immediately the sufferer becomes infected. Elaborating this hypothesis, he states that every epidemic of poliomyelitis is preceded by a "carrier epidemic" in the course of which susceptible contacts are infected and an outbreak of the disease occurs. In any given area the presence of this army of carriers leads to the practically simultaneous mass infection of all available susceptible subjects. Further he states that epidemics of poliomyelitis are characterized by a rapid blaze, high peak and rapid fall, a feature due to the mode of spread he describes. In such semi-isolated communities as country villages or boarding schools this manner of spread implies the universal and simultaneous staining of all susceptible members of the community and precludes the further extension of the disease within the community with the result that all those not initially infected may safely remain within the infected community. The practical bearing of this conception is that all such communities should be kept together on the appearance of poliomyelitis within them and segregated from the surrounding society.

Since this hypothesis raises vitally important questions of public health and departs from the generally accepted body of teaching, it is essential that the data on which it is based should be carefully studied. Briefly, as formulated by Collier, these are (1) the literature of the disease records no authentic example of case-to-case infection. Multiple case within households are rare, and spread from a patient in a hospital ward is unknown. (2) The "rapid blaze, high peak and rapid fall" of epidemics of poliomyelitis can be explained only on the basis of a preceding "carrier epidemic" and does not accord with case-to-case spread. (3) Finally there is the categorical statement, for which no evidence is submitted, that at the moment of infection the virus ceases to be infective, thus rendering case-to-case spread impossible.

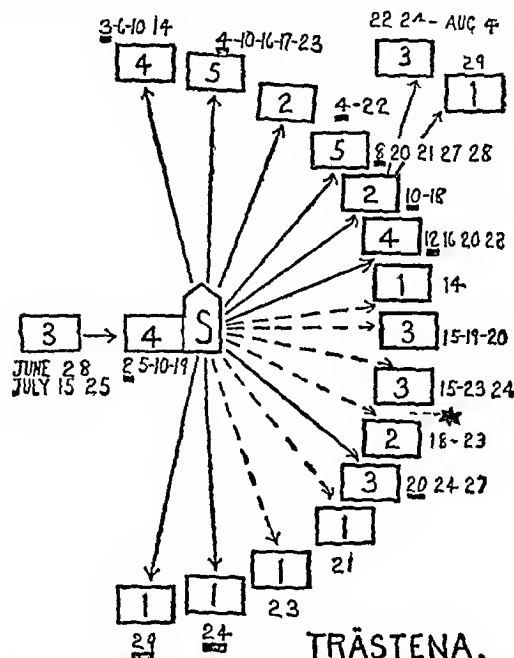

Before proceeding to discuss the first two postulates let us summarily dismiss the third. It has been established by Flexner and Amoss that the nasopharyngeal secretions within the first ten days of onset of the disease contain a virus not less infective for the monkey than is that of a healthy carrier. For this susceptible animal there is then no loss of virulence. In the circumstances it is incredible that there should be a selective loss of virulence for the other susceptible animal man. Throughout the whole range of infective agents pathogenic to man there is no parallel for the state of affairs thus alleged for the virus of poliomyelitis and in the absence of evidence we may dismiss it as a speculation incompatible with the facts.

It is perhaps more difficult to establish unequivocally the occurrence of case-to-case infection despite the strongest indications, it is always easy to maintain that somewhere in the background is the healthy carrier who is in fact responsible for spread and while it may be impossible to demonstrate his existence at the relevant time and place it may be equally impossible to exclude it. Nevertheless we may reasonably object to the invocation of this factor in respect of every epidemic unless there is more substantial evidence of its operation than our inability to prove a negative.

In referring to the literature for examples of case-to-case infection it is essential to go direct to original sources in which all the facts of observation are recorded irrespective of their possible bearing upon the question at issue. For this purpose we cannot do better than turn to Wickman's original monograph on the Swedish epidemic of 1905. Wickman concluded upon evidence which left him no alternative that poliomyelitis tends to spread along the lines of human traffic borne thereon by healthy carriers of the virus and by sufferers from the disease more particularly during its initial phase and in its abortive form. Suspended as he was by the importance of the healthy carrier he drew attention to the equally important role of the infected patient. Amongst the numerous foci of the disease analysed by him those in the parish of Trastena and on the islands of Sirko and Borgo provide clear examples of a state of affairs incapable of explanation on

\* These remarks were made in opening a discussion on the notifiable infection, i.e. of the nervous system at the Annual Congress of the Royal Sanitary Institute, July 1927.

the basis of a preceding "carrier epidemic," and establishing beyond reasonable doubt the preponderant role of case-to-case infection. The accompanying figure is a diagrammatic representation of the Trästen outbreak, modified from Wickman's diagram.

The rectangles represent houses, and the figure included within each is that of the number of cases of poliomyelitis in the house. Beside each house is given the dates of development of each case. Except in respect of the first and last cases the month is July. S = the school and attached schoolhouse. The arrows represent direction of spread, and those with interrupted lines indicate house holds infected by a healthy carrier. In the other house holds the initial case was a child actually attending school. The asterisk indicates the date (July 15th) on which the school was finally closed. (Modified from Wickman's Figure 2)

In 1905 Trästen was a remote woodland village of some 500 inhabitants living in 119 houses, 49 cases of poliomyelitis occurred in nineteen houses, the first case developing on June 28th, and the last thirty-seven days later, on August 4th. The maximum number of cases developing on any single day was 4. Multiple cases in households were the rule, occurring in no fewer than thirteen of the nineteen infected houses. The maximum number of cases in a single house was 5. In the first eight households infected the initial case was a child attending school. The school was infected by the first case in the village, and the schoolhouse was the second household involved, four of the schoolmaster's children developing the disease. From this point household after household was infected, in six instances a school child who remained healthy carrying infection home from school. In nearly every instance an incubation period of three days or over intervened between the appearance of successive cases within a given household. The school was closed on the 15th of the month, and after that the epidemic rapidly declined.

Here we have a characteristic example of gradual spread of the infection within a semi-isolated community, the school being the centre of infection. The day-to-day case incidence both in the village as a whole and within individual households indicates a case-to-case spread, and is incompatible on the basis of a preceding "carrier epidemic" and simultaneous infection of all available susceptible subjects.

In another outbreak cited by Collier himself we find evidence of the same order as that provided by the Swedish epidemic. I refer to the outbreak of poliomyelitis in the Devon village of Stokes Rivers in 1911. At the relevant time this village contained 119 inhabitants living in eighteen houses. There were reported 36 cases of the disease, occurring in fourteen houses. Four houses, containing 8 children, escaped entirely. The main facts of the outbreak are as follows. The thirty-sixth and last case developed a late as forty days after the first, not more than 2 cases developed on any one day, multiple cases occurred in

eleven of the fourteen infected households. In one house 9 cases occurred during a period of twenty-two days, with a definite incubation period between the onset of each. Collier's summary of this outbreak—namely, that it was "a swift scourge, which, lighting upon the little village of Stokes Rivers, could lay low in a few days 45 persons out of a total population of 119," is so out of harmony with the facts as to lend no support to his theory.

Finally, Burrows and Paik<sup>3</sup> have analysed a very interesting small outbreak in a block of flats in an American city which provides further convincing evidence of the important role of case-to-case spread in epidemic poliomyelitis. In this instance 10 children out of a total of 18 were successively infected after exposure to preceding victims in the series.

These outbreaks are characterized by a complete lack of the features held to establish the exclusive role of the healthy carrier and the occurrence of a preceding "carrier epidemic" in the epidemic incidence of poliomyelitis. They show neither a "rapid blaze, high peak, and rapid fall" nor any subsequent immunity of susceptible subjects not infected at the outset. Multiple cases appearing successively within a single household predominated over single cases, while susceptible subjects proved liable to infection, with its attendant risks to life and limb, throughout the whole period of their stay within the infected community and until the epidemic had finally smouldered out.

If we consider the special case of a semi-isolated community of young children, containing in all probability a high proportion of susceptible subjects, there seems no doubt that their retention within an infected community is fraught with considerable risk of infection throughout the entire period of their inclusion.

The theory of the "carrier epidemic" and the exclusive infectivity of the healthy carrier, therefore, falls to the ground, and the practical bearing thereof is that the keeping together of a community in which poliomyelitis has appeared is dangerous to every member of the community in question, and cannot be regarded as a scientific measure of preventive medicine.

We must continue to hold, therefore, that Wickman's theory of case-to-case and carrier infection in poliomyelitis is correct, and must be the basis of procedure when epidemics occur. That there are no published records of the spread of the disease within hospital wards, either by carriers or by sufferers, cannot be interpreted as excluding case-to-case infection without also ruling out carrier infection. In any case the argument lacks force, since there are obvious factors contributing to this lack of hospital examples. For over twenty years poliomyelitis has been generally recognized as a contagious disease, and children admitted to hospital suffering from it in its acute phases are treated with the precautions usual in cases of infective disease, and their opportunities of spreading infection are restricted in consequence.

The question has also been approached from another point of view by Aycock and Eaton,<sup>4</sup> who, making a comparative study of the incubation periods of measles, scarlet fever, and poliomyelitis, find that in each disease incubation periods fall into two distinct groups, a short and a long. The former indicates simultaneous infection from a common source, the latter indicates two secondary cases to case infection. On this basis, although two secondary cases of poliomyelitis are less common than those of the other two diseases, their occurrence seems undoubted.

There remains the question of non-human carriage and spread of the disease. From his analysis of a large series of cases Aycock<sup>1</sup> has come to the conclusion that transmission by human contact appears inadequate to account for some of the features of the epidemic occurrence of poliomyelitis, and that spread may occur in the apparent absence of this factor. He suggests the existence of non-human modes of spread, and indicates milk as one such possible agency for the carriage of the virus. He has subsequently reported, with Knapp and Godfrey,<sup>5</sup> a small outbreak in which there was evidence that milk may act as a vehicle of infection. Of this outbreak of ten cases, these authors remark:

"As to the Cortland outbreak, we would point out that in only cases to occur in a city of 15,000 people subsequent to the

appearances of the disease more than two months previously were with one possible exception in persons who drank milk from one local source older than 3 per cent of the city's total supply that the cases were distributed widely enough to make it improbable that the milk supply to be a mere coincidence of geographic distribution. When to these facts we add that an actual paralytic case of the disease existed on the dairy farm from which most of the milk came that this patient was milking the cows and handling the milk for a period of four days while in the acute stage of the disease and at the time which elapsed between this period and the dates of onset of the subsequent cases were consistent with the generally accepted minimum and maximum incubation periods of poliomyelitis the chain of circumstances is as complete as is found in the majority of milk-borne outbreaks of the disease. While this outbreak point to transmission by milk we are of opinion that this is not the usual mode of spread of poliomyelitis.

In such outbreaks as are characterized by indications of common source or virus infection, therefore, such a non-human mode of spread must be considered. The sudden outbreak of poliomyelitis in a Kent sea-coast town last year comes to mind in this connexion, and suggests the possibility of such a mode of spread. It would indeed be unfortunate if an uncritical acceptance of the hypothesis of a preceding "carrier epidemic" were to lead to any omission to investigate scrupulously every possible means of transmission, non-human as well as human, of this dread disease. One of the most striking dangers of speculations of the kind is that they are apt to make us think that we possess an adequate explanation of phenomena which are, in fact, extremely obscure in their causation, and thus to lead to a slackening of that rigorous and exhaustive search by which alone knowledge is to be gained.

## Memoranda:

## MEDICAL, SURGICAL, OBSTETRICAL

## TWO CASES OF INJURY TO THE CERVICAL VERTEBRÆ

The two following cases of injury to the cervical vertebrae—one of them ending in death—seem worthy of record. There seems little doubt that in the first the nerve symptoms though absolutely symmetrical in the upper limbs did not result from cord injury, as the result of fracture of the sixth cervical vertebra, but from bilateral identical injury to the brachial plexus. All cords were involved, but mainly the inner, the injury to none being sufficient to abolish sensibility. The nature of the injury the method of its production, and the complication of a fracture of the cervical vertebra make the case interesting and unusual.

## Case 1

A man aged 53 whilst fishing fell from a bridge a distance of about 12 feet landing upon his head. He did not lose consciousness.

On admission to Bristol General Hospital on March 21st 1927 he had a scalp wound extending for about 7 inches over the fronto-parietal region with no skull injury. Neck movements he performed with ease but complained of no pain in that region. Both wrists were dropped with complete loss of power. The thumbs were slightly abducted and the fingers held flexed at the inter-phalangeal joints and extended at the metacarpophalangeal joint. His grip was extremely feeble equal—so on both sides. Shoulder and elbow movements were weak and sluggish. Anaesthesia was absent in both hands and arms, the patient being able to appreciate a touch with wool but he complained of a tingling sensation passing from his wrists to his fingers.

Abdominal reflexes were present, the kneejerks were normal and equal on both sides, the plantar reflexes were flexor. There was no loss of function or power in the lower limbs and there were no sensory changes.

The day following admission to hospital his temperature rose to 102° F and his pulse from 64 to 93. He became dull and towards evening he was slightly delirious. The pupils remained unchanged. He had no passed urine. The third day his mental apathy continued, and there was oedema of forehead and cheeks extending down both sides of the neck and affecting most of the posterior triangle. He lay with his arms across his abdomen. He passed urine small and a normal reaction of his bowel had taken place. X-ray examination showed an oblique fracture of

the body of the sixth cervical vertebra with a slight degree of compression.

From the day he commenced to improve. The weakness and stiffness in his arms gradually disappeared. He became able to move the wrists but his grip was still feeble. There were no abnormal urinary or bowel symptoms nor at any time evidence of any affection of the lower limbs. After six weeks in hospital he was discharged as a walking patient wearing a neck plaster, the only remaining symptom was a rather weak hand grip.

## Case 2

A youth aged 21 fell from a roof on to the back of his neck. He was very dazed but not unconscious. On examination in the out-patient department he was found to have a small cut on the back of the head. He was quite conscious and complained of pain in the neck and down the right arm. Movements were free and there were no sensory changes. He refused to remain in hospital.

The following day he walked to the out-patient department but his symptoms having become worse he was admitted to hospital. The pain in his neck and arm was still present but he now held his head stiffly and turned toward the left. Part of the right arm was marked but no sensory change could be elicited. That same evening he suddenly collapsed and died. Post-mortem examination revealed a fracture of the posterior arch of the atlas with some oedema and minute haemorrhages in the cord.

I am indebted to Professor F. W. Hey Croves and to Mr. Danen Wood for permission to publish these cases.

JOHN J. ROSS, M.C. MB, F.R.C.S. Ed.,  
Surgeon in Charge Bristol General Hospital.

## CARCINOMA A COMPLICATION OF PILLS

It is not unusual to see piles the result of carcinoma, but the following case illustrates the reverse condition.

A lady aged 62 had been operated on for piles fifteen years previously but the symptoms recurred about nine months ago. The clinical features were characteristic of external and internal piles which became inflamed and prolapsed at intervals. A light amount of blood and a little mucoid discharge were noted. In addition to the prolapsed internal haemorrhoids several external piles were present but one was larger and firmer than the others. It seemed to be an organized thrombosed pile with considerable inflammatory thickening and slight ulceration of the surface. The inguinal glands were not enlarged.

At operation the possibility of the pile being malignant was considered and its excision with a fairly wide margin of skin and mucosa was carried out in conjunction with the operation for the prolapse. The base was not adherent to the external sphincter.

On section the usual structure of an organized thrombosed pile was seen but in addition the surface skin showed definite malignant changes—squamous-celled carcinoma with cell nests and ingrowth of epithelium and round-celled infiltration. Subsequently bilateral inguinal adenectomy was performed but the glands showed no sign of invasion.

I examined the patient six months after the first operation and found no sign of recurrence.

This case illustrates the importance of submitting to microscopic examination all tissues removed at operation. Without it this condition could not have been diagnosed. More recently I met with a case in which there was advanced leucoplakia of the skin overlying an external pile—presumably a pre-cancerous condition.

I am indebted to Mr. K. W. Monsarrat, surgeon to the Northern Hospital, Liverpool for permission to publish these notes.

PHILIP HAY, M.B., Ch.B. F.R.C.S.,  
Surgeon to the Northern Hospital, Liverpool.

## LONG UMBILICAL CORD COILED ROUND NECK

The following case of an unusually long cord coiled six times round the neck appears worthy of record.

A multipara aged 23 was delivered of a full-term female child weighing 5½ lb. in University College Maternity Hospital on July 17th 1927. Vaginal examination ten minutes previous to the delivery showed the head in a deflexed attitude, the anterior fontanelle being well down. The position was right occipito-anterior. After the head was born one loop of cord was pulled over it before the rest of the child was raised. The precipitous delivery was then very then five more coils round the neck. The length of the cord was 53 inches (147 cm). The insertion of the cord was central and the placenta and membranes were complete. No sign of foetal distress were apparent before delivery and the child commenced breathing quite normally when born.

The average length of cord is given as about 50 cm, and the limits are from a few millimetres to 183 cm. The source of this much quoted figure is Hertel's book *Die Placentar- und Nabelkrankheiten* (1870). De Lee (1913) states that cords over 100 cm in length are very

McCaffrey (1927) has collected five cases in the literature in which there are more than four coils round the neck, the highest number being observed by Gray who in one case found as many as nine. McCaffrey himself found three cases, in a series of 3,000, with four coils. His statistics go to show that coils are more frequent in multiparae and in right-sided positions.

This case, too, is an interesting example of pinning down of the head caused by multiplicity of loops of cord round the neck. Fortunately the small size of the head prevented this from obstructing the normal course of the labour.

I am indebted to Professor F. J. Browne, Director of the Obstetric Unit of the Hospital, for permission to publish the facts of the case.

S. ZUCKERMAN, M.A.

University College Maternity Hospital London

### PYREXIA WITHOUT VISCERAL SIGNS

ATTENTION was called recently by the lay press to the occurrence of a pyrexical illness without involvement of the chest or obvious physical signs.

Late on the evening of August 6th I was called to a public school boy aged 18 who complained of feeling unwell and of headache and feverishness (his temperature was 102°). The bowels had

been open that day, the tongue was very slightly furied, the skin was clammy and moist. There was no abdominal tenderness, and nothing abnormal was detectable in the chest. The respirations were 22, the pulse 102.

He was given two grains of salol and was directed to take a saline draught in the morning. The effect was good. The tongue cleared up, and for the remainder of the time

was moist and rather unusually red. On August 7th he still complained of headache and of feeling generally rotten, and also of occasional very slight joint pains. He was given a simple dia-phoretic mixture and was tepid sponged twice a day. The chest never showed any signs at all, slight tenderness behind the ear the site of old mastoid trouble, was complained of on August 14th and 15th but passed away. From August 10th onwards he had a salicylate mixture (10 grains) and salol (5 grains), both three a day, the course of the disease is shown in the temperature chart. The pulse was dirotic on August 13th. Convalescence was uneventful.

I am rather inclined to view the case as a slight manifestation of intestinal influenza.

Bickley, Kent

CHARLES A. H. FRANKLIN, M.D.

### INVERSION OF THE UTERUS

As inversion of the uterus, though not rare, is still an uncommon accident (Dr. T. W. Eden states that it is only met with in from 1 to 180,000 to 1 in 200,000 labours) it seems worth while to record the following case.

On July 5th 1927 I received a form from a midwife to attend a multipara aged 38 years for retained placenta. On arrival I was given a history of normal labour as far as the end of the second stage when an average female child was delivered. During the third stage the placenta had come away incomplete and the patient had collapsed. Further portions of the placenta and membranes had then come away but the midwife feeling a mass in the vagina and observing the state of the patient, decided to obtain medical assistance.

I found the patient with well marked symptoms of shock and almost pulseless. Haemorrhage was only slight. She was conscious and complained of faintness but there was no pain. A hypodermic injection of 1 ccm. adrenaline was immediately given and brandy and saline by the mouth. On bimanual examination a firm mass was felt low down filling the vagina and abdominally the absence of the hard fundus and body of the uterus and in its place the inversion ring made the diagnosis of almost complete inversion of the uterus apparent.

Under ether anaesthesia an unsuccessful attempt was made to reduce the displacement. The patient was then admitted to the Barry Accident and Surgical Hospital, where she died later in the day from shock. No strenuous efforts were made to expel the placenta and the cord was of average length, so the condition would appear to have been spontaneous probably due to atony of the wall of the fundus uteri.

## Reviews.

### THE PROBLEM OF PLAGUE IN SOUTH AFRICA

A CONSIDERABLE amount of attention has been directed of late to the subject of plague in South Africa (*BRITISH MEDICAL JOURNAL*, February 26th and May 14th, 1927), and, indeed, it is a question of importance not only for South Africa itself, but for all countries having commercial transactions with it, for the effects of plague, commercially or medically, are always felt beyond the confines of the country where it happens at the time to prevail.

A recent publication<sup>1</sup> (No. XX) of the South African Institute for Medical Research comes most opportunely to bring the whole question again before the medical world. This work is the result of the joint efforts of Dr. MITCHELL, the chief health officer for the Union of South Africa, Dr. HARVEY PHILLIPS, bacteriologist of the Research Division, and Dr. INGRAM, medical entomologist to the Institute. The work forms a complete and up-to-date exposition of the problem from the two aspects of the history of the disease in the country and the reasons for its prevalence. It is divided into eight sections, for all of which, except the first and last, Dr. Harvey Phillips is responsible.

Section I is the most interesting to the generality of people outside South Africa, for it gives a most interesting account of the distribution and prevalence of plague in the Union from the time of its first recorded appearance at the beginning of 1899 (when it was imported from Madagascar to Lourenço Marques and by Delagoa Bay) down to June, 1926. The author of this section, by virtue of his position, put forward in May, 1924, a scheme for a comprehensive investigation involving the organization of a mobile laboratory and a special research staff for work in the field. The results of these investigations are recorded in the remaining sections of the book. Section II contains notes on the various rodents associated with the disease in South Africa, describing their distinctive characters, their ranges of activity, and sketching briefly their habits. Sixteen species of wild rodents are described, of which eight have been found naturally infected. It is the great variety of these that constitutes one of the main difficulties in dealing with the problem. The incidence amongst the human population would doubtless be much more severe than it actually is were it not for the fortunate fact that the species of fleas found on veld rodents very rarely occur on domestic rodents.

In the succeeding section is recorded a series of tests carried out with the view of determining the comparative susceptibilities of the various species of rodents to plague. This is an important piece of work, performed with the care and skill which we have come to expect from the staff of the Research Institute. All proved to be highly susceptible, except the Namaqua gerbille (*Desmodillus auricularis*), a fact which may be of great importance in delaying the spread of plague in the northern and western parts of the Cape Province. The various species of *Komodo* rats, formerly believed to be relatively immune, proved to be as highly susceptible as the rest, the difference in their habits and their ectoparasites is the reason of their diminished liability to plague. The common gerbille (*Tatera lobengulæ*) and the yellow mongoose (*Cynopsis penicillata*) occupy the two extremes, the former constituting the chief reservoir of plague on the veld, the latter being extraordinarily resistant to infection.

The question of plague on the veld and its persistence is next taken up, and it is shown that the disease may die down and become for a time quiescent among the rodents, and that certain fleas could infect as long as four months after leaving an infected host. A bacillus, the "Tiger River bacillus," so named from the place of its discovery, and scientifically denominated by the author *Lysterella hepatolytica* (which may be identical with *Bacterium monocytogenes* discovered previously by E. G.

<sup>1</sup> The Plague Problem in South Africa. History and Entomological Studies. By J. Alexander Mitchell, D.P.H. Cantab., J. H. Harvey Phillips, B.Sc. FRSE and A. Ingram, M.D. Edin. Publication Institute for Medical Research, No. XX, Johannesburg, 1927. (7½ x 10" pp. 152-26, 11 plates.)

Murina at Cambridge) causes a fatal infection among gerbilles, and a certain degree of success is reported from the use of this, on the lines of the Drury virus, for destruction of plague-carrying rodents.

Section VI is of great practical value, in that the results deduced from animal experiments as to the benefits of prophylactic vaccines and serums tend to show that the sense of security engendered by their use on theoretical grounds rests on an unsure foundation. Of particular interest is Dr Pirie's statement that neurochrome proved valueless in his hands for treating plague in guinea pigs.

The final section, by Dr Ingram, on the entomological aspect of plague in South Africa, is a detailed record, mostly of field work carried on during 1925-26. An enormous amount was done, and the account of it is given in several subsections. From a practical point of view the chief subjects were the identification of the numerous species of fleas collected from different rodents; experiments to test longevity, others to test the capability of fleas of conveying plague from one rodent to another, and the seasonal prevalence of the commoner fleas caught on wild rodents and those found on house rats in Johannesburg.

The compilation will be of great service in clearing up past misconceptions and in indicating the lines along which this vast and important problem may best be attacked in the future, and all three authors are to be congratulated on a very fertile piece of team work conscientiously performed.

### PRESSEY'S "MENTAL ABNORMALITY AND DEFICIENCY"

ILLNESS is as social as well as a medical problem. Particularly is this the case with mental illness, and if mental illness is understood to connote not merely definite psychoses but all serious emotional and intellectual maladjustments and deficiencies it is clear that there is room for a book offering a wide and not too technical or detailed survey of these conditions. Such a book is *Mental Abnormality and Deficiency* by Professor SIDNEY L. PRESSEY Ph.D., and LUCILA C. PRESSEY Ph.D. Neither of the authors possesses a medical qualification but both are teachers of psychology in the Ohio State University, and have had a rather unusual range of experience in actual work with abnormal and defective children and adults. They have "attempted a treatment which should be of definite practical value to those interested in various special fields of work in which problems of personality and adjustment are frequently met," and their volume should be found of considerable value by social workers by welfare and business superintendents, by school teachers and administrators and college deans, by police court missionaries and magistrates, and by others who take a more general interest in the special problems dealt with. The newly qualified medical man or woman too should find it of service whether the sphere of work contemplated be general practice or the school medical service.

The method of presentation adopted by the authors is largely the case method. The essentials and pitfalls of history taking and the technique of case study are carefully set out. The various main types of mental disease and defect are described, their causes and the methods of dealing with them are discussed, a suggestive chapter on mental hygiene concludes the volume. The writers justly insist upon the wide extent of the problem of mental deficiency, disorder, and disease even when allowance has been made for that lower average intellectual level and wider variation within the limits of the normal which has come to be recognized in recent years, upon the importance of the "borderland" conditions of the emotionally maladjusted, the emotionally unstable and the mentally queer, upon the necessity for regarding individual personality and character among those who as a group are called "feeble minded" upon the fact that "generalizations in psychiatry are risky and should be applied only with great caution in individual cases" and upon the real possibility of the prevention of mental

illness by careful discipline, training and social adjustment in early life.

Different portions of the book will appear of greater value than others to different classes of readers, and it must be confessed that to the English medical reader the value of the whole seems less than it should be, by reason of its entirely American outlook and the absence of actual experience of medical practice by its authors. For example, the Mental Deficiency Acts in this country give definitions of the different classes of mentally defective persons which are legal guides of great practical value and are not far from being scientifically acceptable. These are entirely ignored in the volume under review, which adopts instead standards which, however carefully applied, are apt to be misleading both in diagnosis and treatment. They do in fact result in apparently contradictory statements in the text, and in an estimate of the influence of heredity in these cases which most English authorities would hesitate to endorse. Again, there is no mention of the mental effects of lethargic encephalitis, which recent medical practice in this country has shown to be of very great interest and importance. Though this book thus serves to emphasize the desirability of a volume covering similar ground and written for a similar class of English reader by writers one of whom, at least, should have actual experience of medical practice, this very fact demonstrates how valuable it still is as 'an introduction to the study of problems of mental health'.

### A GERMAN CYCLOPEDIA OF PHYSIOLOGY AND PATHOLOGY

THE first half of the seventh volume of the *Handbuch der Normalen und Pathologischen Physiologie* contains nineteen articles on the physiology of the heart; they cover a very wide field for they deal with the physiology of the mammalian heart with the comparative physiology of vertebrate and invertebrate hearts with the methods of clinical investigation of the heart, and with heart disease. Certain of the articles are of considerable interest and value. Professor Bethle has written well on the comparative physiology of blood circulation, both in vertebrates and in invertebrates, and Professor Hebe has contributed an article on the variations in size of the vertebrate heart, much of the information in which has been collected for the first time. The article by Professor Weizsäcker, on the metabolism of the heart and on its heat formation is of particular interest as it is very largely based on his own original work. There are articles also on the clinical methods regulating the functional activity of the heart; they include essays by Professor W. Frey, on the apex beat and heart sounds, on the heart size by Professor Hans Dittler, and on fibrillation by Professor H. Winterberg. It is impossible to deal fully with a large volume of reference such as this, but in general it may be said that the articles are of a high standard and that the editors have been fortunate in their choice of contributors.

The eleventh volume of this encyclopedia deals with 'organs of reception.' The editors explain that though the older term 'sense organs' may be suitable for use in writings on human physiology, yet in a book which includes comparative physiology any term which bears a subjective implication is objectionable; they have therefore employed a purely objective nomenclature. The volume deals with the following receptor organs: tangoreceptors (touch), thermo-receptors, pain receptors (taste and smell), phono-receptors (hearing), stato-receptors (vestibular apparatus) and concludes with articles on geotropism in plants and animals and galvanotaxis. Special mention may be made of two articles by Professor R. Magnus of Utrecht on the semicircular canals and otolith apparatus in mammals. The articles have a particular interest and authority because they are very largely founded on the brilliant researches carried out during the last ten years in the author's school.

\* *Handbuch der Normalen und Pathologischen Physiologie*. Herausgegeben von A. Bethle, C. V. Perryman, G. F. Minn, A. Ellinger, F. H. J. Springer. 1936. (Sup. vol. 8). Band VII, 1. pp. x + 825. 40 figures. R. 16s. Band XI, pp. x + 1057. 46 figures. P. 18s. Band XIII, pp. xii + 1193. 40 figures. P. 16s. Band XVII, pp. xi + 1204. 173 figures. 1 M. 84.

- *Mental Abnormality and Deficiency*. By SIDNEY L. PRESSEY Ph.D. and LUCILA C. PRESSEY Ph.D. G. Allen and Unwin Ltd. 1936. (Extra P. 4. 8vo pp. xii + 556. 10s. 6d. net.)

The subjects of reproduction, development and growth are treated together in the first half of the fourteenth volume. The first part of the volume contains a series of articles on the physiology of the gonads, and some of the most interesting are those of Professor Knut Sand on estration, the transplantation of the gonads in vertebrates, and the experimental restitution of the gonads in vertebrates. The author, who has worked on these problems for many years, displays a very sceptical attitude regarding rejuvenation by transplantation of the testicles, and emphasizes the fact that even auto-transplants do not last for more than a few months under the most favourable conditions. He points out that the absorption of grafts made from individuals of a different, even though allied, species proceeds much more rapidly. He is more optimistic regarding Steinhilber's operation (the ligation of the vas deferens), for he states that personal experience for four years of both laboratory and clinical work has greatly modified the position of absolute scepticism which he had at first assumed. He now admits that remarkably beneficial results are undoubtedly produced and even appear to be permanent. The article by Professor Biedl on the action of testicular and ovarian extracts also deserves notice, as he gives a full account of the extensive recent researches on this subject. The editors of this cyclopaedia have in all cases taken a broad view of the subjects to be discussed in it, and hence it is not surprising to find the section on reproduction concluding with a series of articles on sexual psychology. The last quarter of the volume is devoted to the subjects of growth and regeneration of tissues.

Volume XVII deals with correlations within the body, and covers a remarkably wide range of subjects. The first quarter of the book deals with heart regulation and water exchange. Articles of particular interest are those on hibernation, by the late Professor L. Adler, on the physiology of water exchange, by Professor R. Siebeck, and on diabetes insipidus, by Professor E. Meyer. In all these instances the authors have extensive first-hand knowledge of the subject, and include in their articles a certain amount of unpublished original work. The next quarter of the volume deals with the action of radiations, light, heat, rays, and radium, together with the effect of climate on health. This section is followed by a few articles on sleep and hypnosis, that by Professor C. J. Irons, on the pathology of sleep, is of outstanding interest. The rest of the volume is filled by articles on old age, death, and heredity.

On the whole, the articles in this cyclopaedia maintain a high standard, but they are open to the criticism that the authors show an undue tendency to confine their attention to German work. A simple count of about 500 consecutive references from half a dozen different articles indicated that about two-thirds of the references were to German work and only one-third to the original work of all the other nations in the world. The narrowness of outlook thus exposed is betwined in several statements we have noted, for example, on page 518 (vol. XVII) the author states "The ultra-violet rays cure rickets. The manner in which this action is produced is still completely unknown." Apparently the significance of the English and American work on the production of the antirachitic vitamin from cholesterol by means of ultra-violet light is still unknown to German scientists of repute, although it has become popular knowledge in this country. Other similar lapses could be quoted. This tendency to a one-sided view of science is particularly regrettable and will hinder the cyclopaedia becoming a standard international work of reference in physiology.

#### IRREGULAR ACTION OF THE HEART

THE work of the Vienna school on cardiac irregularities is well known in this country, and now Professor WENCKEBACH and Doctor WINTERBERG have produced a very comprehensive textbook on irregular action of the heart.<sup>1</sup> It was planned originally as a second edition of Professor Wenckebach's earlier volume on the subject, but, owing to the great accumulation of fresh material since 1914, it is in reality a new work. The early pages deal shortly with

the special anatomy and physiology, and with the methods now employed for investigating the heart's action in the human subject, particularly the string galvanometer. The remainder of the book is devoted to excellent descriptions of the nature, diagnosis, prognosis, and treatment of the various cardiac irregularities. While full reference is made to the observations of other workers the bulk of the material is drawn from the authors' own experience. The teaching does not depart in any essential from that current in this country, the descriptions are clear and detailed, and the numerous good examples of polygraphic and galvanometric tracings are published in a separate small volume.

It is a good book and should prove very useful, not only to those already acquainted with the subject, but also to those who would enter this interesting and important field of clinical medicine.

#### KITCHEN CHEMISTRY

THE second volume of *Applied Chemistry* continues on similar lines the studies begun in vol. I. The contents deal with a variety of foods, including milk, fats, carbohydrates, meat extracts, and various beverages, there is a chapter on cooking and another on the caloric value of foods.

The book is designed for students taking the degree of B.Sc. in household and social science. The reason for the choice of title is apparently that applied chemistry is the name given to a scheduled course of study for that degree, but the title is something of a usurpation, for those engaged in chemistry as applied to agriculture, brewing, ceramics, or dyeing have an equal claim to it, to say nothing of manufacturers of chemicals. It appears further that chemistry as applied to household science is not what we had thought. We had expected to learn something of the chemical changes that occur in culinary operations, how these may be brought to the most desirable pitch, and by what mismanagement they may be ruined. Very meagre, however, are the references to information of this kind, most of the text is occupied with methods for the discovery of adulteration which properly belong to the laboratory where foods are analysed.

In the chapter on cow's milk little more than a page is given to the detail of what milk is, while more than twenty pages are filled with methods for its analytical examination. We would not demur to this scheme if it appeared to be the best way of teaching the nature of the components of milk, but of that we are not convinced. It may be true—we suspect it is—that not much is known of the chemical laws which govern the transformations in our food, perhaps even the distinction between beef tea and chicken broth is too subtle for chemical discussion. But something, we believe, is known of the constituents of the tea leaf and coffee seed, here surely was a chance to explain chemically what has happened when a cup of tea or coffee is made well or is spoiled.

The chapter on the cooking of food does, we agree, introduce the reader to a consideration of the subject on the lines advocated by us, and perhaps something may yet be evolved from this book as a beginning which shall go further in the direction of real domestic chemistry. For the labour bestowed on the book we have nothing but praise. It contains much useful information on a variety of matters connected with the preparation and manufacture of foodstuffs, and if food analysis is to be a subject for the university degree in household science, the book is just what the student needs.

#### NOTES ON BOOKS

DR. TIPPER, who has spent many years in tropical Africa, where he served in the West African Medical Service, has written a little book (its preface is dated from Hong Kong, in the beginning of this year) in which he describes some of the attractions of the great delta of the Niger River. His book, which has for its title *The Cradle of the World and Cancer*, and *A Disease of Civilization*,<sup>2</sup> is the unfolding of a bold speculation. These speculations especially that relating to

<sup>1</sup> *Applied Chemistry*. By C. Kenneth Tipper. D.Sc. F.R.C. and Hon. Member. P.S.C. Vol. II. Foods. London: Crosby, Lockwood and Son (Demy 8vo pp. xi + 276, 20 figures, 2 plates, 15 net).

<sup>2</sup> *The Cradle of the World and Cancer. A Disease of Civilization*. By F. H. Tipp. M.P.C.S. Eng. L.R.C.P. Lond. London: Charles Murray 1927. (Cr. 8vo, pp. 142, 5s. net).

<sup>1</sup> *Die Unregelmässige Herztätigkeit*. Von K. J. Wenckebach und H. Winterberg. Leipzig: W. Engelmann 1927. (Sup. roy. 8vo. Textband, pp. vii + 635, 63 figures, Tafelband, 447 figures, 184 plates. M. 78.)

can't see how this new bit Dr. Tipper contrives to give it a different local colour. He has been much surprised at the order of the great Niger river and its tributaries in the north of its drainage. He counts this as a mistake that this river valley was the cradle of the world and that all the world of men would have been there if only the rest had not been sandered by fire which destroyed the forests and had a waste of the Sahara between the cradle and the outer world. Through that severance he thinks we have lost touch with the first principles of the world and have found a different order since. His original idea is to be such as is easily attainable with the simple agricultural use of a rich tropic valley—vegetables and palm oil and palm wine. But where would the unfortunate native of the high Arctic get these fine vegetable fats or even the inhabitants of the poles of Europe in a fresh and native state? In that valley there is no constipation and no cancer except in rare cases where the people have abandoned their natural food for the flesh pots of the benighted white man. But there is hope even for us—We can at Brighton become copper coloured at the Canaries and if our impoverished blood permits of it and we become acclimatized after a few generations at the Equator we too should be black—and perhaps amely. But in that happy valley there is some use for patients despite the perfect diet. Ancient plants glare at him around him, and need but to pinch off a bit of the fleshy vine growing by the roadside to effect a remedy. So it is certain one of the plagues of civilization cannot exist in that Eden—the patent pill vendor.

After recovering from an unnecessary chilling preamble stating that the London County Council accepts no responsibility for the author's opinions or conclusions, the reader will find that Mr. Deely in his small book on *Industries and Occupations for the Mentally Defective* enumerates some forty five occupations in which he considers the mentally defective can become efficient under trained instructors. They range from simple processes in the making of envelopes, paper bags and needle work to weaving, dyeing, spinning and cement kerling. A short description is written round each, most of them being devoted to manufacturing, shoemaking and weaving. The intention seems to be that all the work should serve the needs of the particular institution or of others controlled by public bodies. The limitations in respect of dangerous processes as in guillotine cutting of paper or cloth in the butchers shop and in tin smiths work are left rather too much to the reader to search out in the descriptions. The medical superintendent of The Manor Epom where the work is carried on says in a foreword that if money could be spent freely on providing suitable work and accommodation and staff there is no limit to the mental occupations of many mental defectives in some direction or other. The book might usefully be read by persons in charge of other institutions than those for which precisely it is primarily intended.

The seventh monograph in the French series of volumes on biological problems deals with aspects of the physiology of the myocardium. The author, Prof. or Henri FREDERICQ, restricts himself to those questions in which he himself has been interested and in five chapters reviews recent work on the origin and propagation of the excitation wave and its electrical manifestations in the vertebrate—especially the mammalian—heart. The book consists chiefly of summaries of the observations and views of the many writers quoted most of which are already known to English workers in the field. A list of nearly 600 bibliographical references is appended.

We have received a copy of *The Insects of Australia and New Zealand* by Dr. R. J. TILLYARD who is entomologist and chief of the Biological Department of the Cawthron Institute, Nelson, N.Z. The work which is intended primarily as a textbook for students of entomology in Australia and New Zealand and secondarily for those who have a general interest in the insect life of these countries, contains thirty chapters. The first four which are introductory deal with the classification and census, external morphology, internal morphology and life history of insects in general. The bulk of the volume is concerned with the various order of insects including sections dealing with morphology, life history, distribution, fossil history, economics and classification followed by keys to the

suborders, superfamilies and families and accounts of all the families in each order. In the penultimate chapter the food, order and origin of the Australian and New Zealand insects are discussed and in the last chapter a brief account is offered of the more important methods for collecting and preserving and for the scientific study of insects. A glossary of biological and entomological terms is appended. The text is freely interspersed with figures 203 of which are coloured.

An English edition of *The Early Embryology of the Chick*, by BRIDGES M. PATTY, has been published in London by John Murray at the price of 1s. The American edition was reviewed in our issue of November 21st, 1926, p. 957.

The Woodward was the first officer under the Lord Warden, and his duty was to inspect the woods. In this capacity Mr. Marcus Woodward in his *Year 1 of Trees* declines, with Oliver Wendell Holmes to hold forth in a scientific way about his tree loves. Instead he tries to bring out the character and expressions of trees and to glean the folklore which has gathered round them. Consequently he divides trees according to the locality in which they grow—woodland, hedge, row, park and seaside and riverside trees with a separate chapter for conifers. The Londoner may be surprised to find the hornbeam of his Epping Forest described amongst hedge row trees. Yet as Mr. Woodward says no tree other than evergreens makes a better hedge plant. Of the maple we learn that Evelyn in describing the value set upon the wood by luxurious Romans for their tables explained that when husbands reproached their wives for extravagance in pearls the wives were wont to retort and turn the tables. Some golfers may not know that the crab apple was once the wood of woods for club-heads though it has now been displaced by the American persimmon. Probably few doctors know that pears were considered an antidote to poisonous mushrooms, a reputation which pears still holds. For each tree there is much anecdote and lore in the book, and the text is sprinkled with quotations from the poets and pleasing wood engravings by Mr. Dillon McGurl. Each chapter is prefaced with a short description of the tree.

*The Year 1 of Trees* by Marcus Woodward, London, A. M. Hughes, L. 1. 1925. (Ditto 8vo pp. 370, illustrated 12. 6d. net.)

## PREPARATIONS AND APPLIANCES

### Temporary Airtight Cases

A simple contrivance for covering cups, mill bottles and small basins temporarily has been sent to us by Acto Ltd. Tudor Works, East Twickenham. It consists of a sheet of thin rubber supported by a metal ring, when placed over the top of the vessel and its centre depressed by the finger it adheres but can easily be moved. It keeps out dust effectively and is likely to be of use in the laboratory as well as the larder. The cost of these vacuum covers which seems to be rather too high varies from 6d. to 1s. according to size.

## ROYAL MEDICAL BENEVOLENT FUND

At the last meeting of the Committee forty nine cases were considered and £770 10s. 8d. voted to forty three applicants. The following is a summary of some of the cases relieved.

L.R.C.S. Edin. 1833, aged 72. Three children all health applicants and his wife have had to live upon their savings which are now reduced to £51. They have no children. He has an Epson pen 10s. 6d. and an old age pension of £25. Pent and rates £25. Voted £40 in quarterly payments.

Daughter, aged 56 of M.P.C.S. Eng. who died in 1837. Has a temporary allowance from brother-in-law of 5 guineas a month and pays £4 8s. to board and room to a widowed sister and helps in domestic duties. She is now recovering from a severe operation and a financial help towards convalescence is voted £13.

Widow, aged 71 of M.P.C.S. Eng. who died in 1837. She has £75 from investments and pays £2 a week for board and lodging. A £1 for help to meet incidental expenses. Voted £15 in quarterly instalments.

Widow, aged 57 of M.D. who died in 1824. Her son trained at horticultural college has purchased a holding and bungalow and she was voted £10 towards its furnishing.

Wife, aged 62, of L.R.C.P. who has been in a mental hospital for twenty four years. Has to support herself by cooking and pay £1 a week towards the board of her invalid daughter who lives with married sister. The Fund has paid the husband a life insurance premium for the past two years. This grant of £9 5s. 8d. has been renewed and £12 has been voted to the applicant for her own expenses.

Widow, aged 66 of L.P.C.P. who died in 1837. She and her niece have a boarding house, but owing to the bad weather have been unable to be and are no in arrears for rates. Voted £13 as a special grant.

Subscriptions may be sent to the Honorary Treasurer, Sir Charles Scrimgeour at 11 Chandos Street, Cavendish Square, London W.1.

The Royal Medical Benevolent Fund Guild still receives many applications for clothing especially for coats and skirts for ladies and girls holding secretarial posts and suits for working boys. The Guild appeal for second hand clothes and household articles. The gifts should be sent to the Secretary of the Guild, 53, Great Marlborough Street W.1.

*Industries and Occupations for the Mentally Defective* by R. P. J. Deely. M.H. A.R.S.L. Epson, Burch and Whittington, 1927. (Cr. 8vo pp. xv + 112, 1 plate, 6d. net.)

*Atropa Atropa de la Phylogenie du Myocardium* (Part 1re Serie) Par Henri Fredericq. Les Presses Universitaires de France, 1927. (Gr. 8vo pp. viii + 393, 2 figures.)

*The Insects of Australia and New Zealand* by R. P. J. Tillyard, M.A. Sc.D. Camb. D.Sc. Sydney, F.R.S. etc. Sydney, Angus and Robertson Ltd. London, The Australian Book Co. 1926. (6 x 9 1/2 pp. xvi + 599 illus. rated.)

# British Medical Journal.

SATURDAY, AUGUST 27TH, 1927

## ALCOHOL AND THE MOTORIST

DURING recent years the influence of alcohol on the driving capacity of the motorist has compelled the serious attention of the medical and legal professions, and has brought into prominence the initial difficulty of devising a sound scientific procedure for establishing the presence and defining the degree of intoxication. The British Medical Association, in October, 1925, appointed a special committee "to consider and report on the present tests for 'drunkenness,' with recommendations as to their modification or improvement." The report of this committee, which was published in the SUPPLEMENT of February 19th, 1927, included an account of the practices and regulations in certain foreign countries, and an examination of the tests in common use in Great Britain to determine the presence of drunkenness, a definition of which was suggested. The committee gave careful consideration to the pioneer work of Dr. Godfrey Carter and Herbert W. Southgate, whose joint paper on the excretion of alcohol in the urine as a guide to alcoholic intoxication was published in our issue of March 13th 1926 (p. 463). The subject was further discussed by the Section of Forensic Medicine at the Annual Meeting of the British Medical Association at Edinburgh, and a report of the views there expressed appears at page 333. Dr. Godfrey Carter, in the opening paper, called attention to the prevailing lack of uniformity in the judicial decisions in cases of motorists accused of being "drunk," and referred to the attempts of Mellanby and Southgate to find a method of determining the amount of alcohol in the system with a view to guiding courts to correct decisions.

The problem is not new, and ought to give little trouble to the medical witness, many of the so-called difficulties arise from the misunderstanding of the question by medical practitioners. The first stumbling-block is, undoubtedly, the vague use of the word "drunk." The man who is drunk—using the word in the lay sense—presents no difficulty, his condition is obvious, and he is usually arrested before he has caused any damage. In fact accidents caused by such drivers may almost be neglected in considering this subject from the point of view of medical evidence. The dangerous driver is the man who has dined well with some friends, he is usually a good if not an expert driver who, owing to his exuberance, takes unnecessary risks. Such a man cannot be said to be drunk in the lay sense—indeed, he may only have had a small amount of alcohol, yet he is drunk in the legal sense. A medical witness using the term

"drunk" is immediately asked to explain what he understands by it, and is generally unable to give any description which will conform with a jury's conception of a drunken man. To avoid this pitfall many employ the phrase, "under the influence of alcohol," which is also bad, since anyone who has taken any alcohol is under its influence. The difficulty vanishes when it is realized that in this connection a man is drunk within the legal meaning of the term when he has become so affected by alcohol that his judgement as a driver has become impaired. It makes no difference

if, owing to some nervous or other disease, it only required half a glass of whisky to produce this effect or whether half a bottle was consumed; the man is drunk within the legal meaning. It is a matter of common knowledge that it is not merely the amount of alcohol that has been consumed, but also the circumstances, the individual and the environment, the time since the accident, and many other factors, which determine the diagnosis of drunkenness. Such a decision can only be an expression of the personal opinion of the medical practitioner, founded on a general clinical examination and his previous experience of such cases. It is for the court to decide the weight to be attached to any particular doctor's evidence. Not realising this many medical witnesses create for themselves further difficulties by elaborating tests, such as walking along a straight line, standing on one foot, or repeating some difficult phrase—facts which some sober persons cannot perform. Anything in the nature of a test can, in almost every case, be ridiculed in cross-examination, after which the evidence of the witness ceases to be of much value to the court.

Conclusions based on determinations of the proportion of alcohol in the blood and urine, to which Dr. Carter's opening paper was largely devoted, are likewise open to serious criticism. Apart from the possible illegality, mentioned by Professor J. T. J. Morrison, of obtaining specimens of urine for examination without the consent, or even without the knowledge, of the accused person, it is undeniable that certain types of individuals give fallacious results. There is the difficulty of obtaining the specimen, and the fact that, even if an analysis should indicate the amount of alcohol consumed, the effects on different persons vary to such an enormous extent with the individual and the environment, both in the amount of alcohol required and in the type of effect produced, that little can be deduced from such an examination other than that a definite amount of alcohol has been imbibed—a fact which may be discovered more readily by other means. The speed with which a man can react to a stimulus, such as the sight of an approaching obstacle, and the celerity of his response, are admittedly variable in different persons, and in the same man at different times, it is not likely that the modification of this response by alcoholic poisoning of slight degree is constant for humanity as a whole. It would seem to follow that the percentage of alcohol in the body fluids is not necessarily a reliable index of the resulting degree of intoxication.

The offence of driving a car while the judgement is affected by alcohol, whether or no the contributing factor of disease is present, is a serious one, and merits severe punishment. In Denmark the question has been carefully studied, details of the medical examination made in that country were published in an appendix to the report of the committee of the British Medical Association. Briefly, it may be said that this examination lasts about three-quarters of an hour, and practically consists of a general clinical examination, urine and blood tests have been considered and discarded. The accused person is described as intoxicated, slightly under the influence of liquor, or sober. On conviction a driver forfeits his licence for life. This punishment is very drastic, and with a penalty so severe there must be a tendency on the part of the court to hesitate to convict. Although this question of punishment is beyond our province, it serves to emphasize the responsibilities of the medical practitioner in these cases, and is a reminder that a diagnosis of drunkenness must not be given lightly.

## A TREATMENT FOR ASTHMA

THE work of Icken in St. Mary's on the cutaneous reactions obtained with extracts of pollen in patients subject to hay fever had received comparatively little notice when Walker of Boston began his investigations on the similar reactions obtained with other proteins in asthmatics. The early expectations that a new era in the investigation and treatment of asthma had dawned were not fulfilled as with very few exceptions later investigators failed to confirm Walker's results. Amongst the visitors to his laboratory in the summer of 1919 was Professor Storm van Leeuwen. He also, when he tested the principle clinically, was able to obtain the positive results claimed by Walker only in a very small percentage of cases. Recognizing however the importance of the theoretical basis of Walker's work, he continued it in other directions. It is the result of these investigations which he has summarized in his article in this issue (p. 344).

There can be no doubt that he has discovered a very important exciting cause of asthma in the moulds which occur so extensively in house dust and elsewhere. A curious contradiction, however, presents itself for explanation. Whereas Mr. Frank Cole, almost the only writer in England who still has an unimpaired faith in the value of cutaneous reactions, advises the use of duck in pillows to replace the feathers to which he believes many asthmatics are sensitive, Professor Storm van Leeuwen finds that *Claviceps purpurea*, which flourishes extensively in kelp, is one of the chief causes of asthma in Holland where the majority of mattresses are stuffed with this material. As, however, in the Swiss mountains where almost all asthmatics are free from symptoms, both feather and kelp pillows can be used with impunity, a doubt whether either is really of any importance as an exciting cause of asthma seems not unreasonable.

The results of the practical application of Professor Storm van Leeuwen's views in the form of his allergen-free chambers requires careful consideration. The fact that exactly the only places which can live in rooms of this kind makes one wonder if after all the atmosphere can be a healthy one for human beings whether asthmatic or not. Moreover it is the experience of every physician that the large majority of asthmatics get well directly they are admitted to hospital; the proportion cannot be much different from that given by Professor Storm van Leeuwen for patients admitted to his clinic. There is nothing peculiar about a hospital in this connection as any change—sometimes even a transient one long ago pointed out to another house in the same street—may be enough to give temporary freedom from attacks to most people suffering from asthma.

Still more important is the fact that the freedom from attacks which follows almost any form of treatment—be it the cauterization of the nose (Francis), desensitization to certain proteins (Walker, Cole), diet (Allen), or care at Mont Dore, a visit to the Alps, or allergen-free rooms (Storm van Leeuwen)—is very different from a cure. The asthmatic constitution remains, and with it the tendency to asthma.

Still any means of avoiding attacks is welcome for as has been said the only cure for asthma is not to get it, and if Professor Storm van Leeuwen's investigations prove that the moulds in house dust are yet another factor which can be dealt with he will have earned the gratitude of every asthmatic.

As will be seen, Professor Storm van Leeuwen is sanguine that his method may be of use in the treatment of pulmonary tuberculosis. The clinical facts he has to present are few in number, although no doubt carefully observed and recorded, and the theory by which he would account for the improvement he has observed in a certain number of cases is not very clearly expressed. Apparently he would attribute it to the removal of the seasonal irritation due to the climatic allergens.

## APPROVED SOCIETIES AND CLINICS

THE actions of approved societies in connexion with those additional benefits under the National Health Insurance Acts which are commonly known as the treatment benefits require to be carefully watched. It is important to note that these benefits consist not in the provision of treatment services or appliances, but in the payment of the whole or part of their cost. The legal position is held to be that so long as any additional benefit involves mere payment of money it is not in the nature of medical benefit and may therefore be administered by an approved society, but that if anything beyond this mere money payment is involved (such as the provision of particular doctors or the establishment or administration of a service) then the benefit would become in the nature of medical benefit and statutorily would have to be administered by Insurance Committees or whatever bodies may be made responsible for the administration of medical benefit. It is clearly a departure from the spirit of the Acts, and even yet it may possibly be held to be contradictory to their meaning, that when these contributions of money go directly to secure service of a medical nature they should nevertheless be administered by the approved societies. The dividing line may with some uncertainty and care be respected in words, but in practice it may very easily be obliterated or overstepped. In these circumstances certain of the approved societies, in order to secure for themselves more freedom and power and having no doubt honestly persuaded themselves that it was in the interest of their members, adopted what may, without offence, be called the dodge of creating a new society purporting to be a charitable institution, under their own auspices and controlled by their own officials, to which they could make money payments but which might be free to do what the societies as such could not do—namely, appoint and dismiss doctors, set up clinics, or provide treatment for their members in any way that might seem to them fit. There is grave doubt whether such a society is in law, a charitable institution, and whether it can legally perform the functions assigned to it. Indeed so grave is the doubt and so important the issue that a legal decision on the matter ought to be secured without delay, the issue of securing it upon private societies and private funds. It may even yet become essential to secure such decision but the necessity would be avoided if the policy desired and assured it by the medical profession and endorsed by the Royal Commission on National Health Insurance were adopted—the thing of these treatment benefits out of the category of additional benefits altogether and transforming them into normal statutory benefits. This would be accomplished by setting up a consultant and specialist service with laboratory facilities, as strongly recommended by the Royal Commission and urged by the British Medical Association. The

idea of establishing such a service has, however, been abandoned by the Government owing to the persistent objection and obstruction of approved societies.

It is not unnatural, therefore, that recent announcements and indications of the action of approved societies, whether open or camouflaged in the way described, should be viewed with a certain amount of suspicion. It is stated, for instance, that "arrangements have been made by some of the largest of the approved societies to establish a central dental clinic in London, and it is hoped that this institution will be opened before the end of the year. The societies have no power to expend their funds on the building and equipment of a dental clinic, but an organization with which the societies are associated has made itself responsible for the undertaking." The plan of establishing one large clinic for the whole of a place like London is certainly open to criticism on several grounds, the auspices under which it is to be established are not the most desirable in the public interest, and the arrangements in accordance with which it is to be organized and conducted are of the first importance professionally. These things are primarily the concern of the dental profession, but a desire to place medical experience in matters not wholly irrelevant at the disposal of others, and the possibility of the establishment of conditions medically undesirable, which hereafter may by some be held to be applicable to clinics other than dental, justify a word of warning.

The nearest analogue is that which is known as "ophthalmic benefit." The arrangements with regard to this benefit have not been working with complete satisfaction. On the one hand some of the approved societies have been finding it expensive, and on the other insurance practitioners can never consent to cover the unqualified practice of opticians, mainly because this may constitute a grave danger to their patients. These objections should be sympathetically considered on both sides. We believe the seriousness of the latter is recognized by the majority of the larger approved societies and certainly the medical profession should do whatever it can to meet the former. The British Medical Association has always held that these treatment benefits should be conducted as far as possible on the lines of private practice, that the general practitioner should recommend, that there should be choice of consultant or specialist, and that the consultation should take place either at the rooms of the specialist or, if necessary, at the home of the patient. So far as the profession is concerned, these are the arrangements at present authorized for ophthalmic benefit, a reduced fee being charged to insured persons. It is not beyond the bounds of possibility that this reduced fee might be further modified in some way in order to meet the point of cost, but it is not unlikely that in certain circumstances some arrangement on the lines of a clinic might be found economical and convenient. A few ophthalmic clinics have been set up by "an organization with which the societies are associated" and an extension of these is talked of. The Representative Body at Edinburgh, on the recommendation of the Council, approved "the principle of providing ophthalmic benefit through clinics in large centres" (that is, of population) "as an arrangement auxiliary to the existing scheme of attendance by ophthalmic surgeons privately, subject to the arrangements under which such clinics are established being approved by the Council." The qualifying phrases of this resolution are important—*ie*, indeed, of the essence of the matter. The present arrangement is not to be aban-

doned but helped, and the conditions under which the auxiliary clinics may be established are to be the subject of careful consideration before they can be approved. Such consideration will no doubt be given at an early date by the Committee advising the Council of the Association, and by the Council itself. The matter is one of some difficulty, but it is clear that neither the auspices under which, nor the conditions in accordance with which, the London dental clinic is to be established can be taken as applying to any ophthalmic clinics which may be in contemplation.

#### THE FINANCIAL AMNESIA OF MOTORISTS

A somewhat complicated discussion has been carried on lately in the correspondence columns of the *Times* under the heading "Motorists and doctors' fees." The ball was opened by a medical man who signed himself "Hire-worthiness", he complained that private practitioners hardly ever received a fee for their services in rendering aid to persons injured in motor accidents. He made the ingenious suggestion that every motorist should be compelled, when paying his licence, to purchase a voucher for a guinea. In the event of injury while driving, the motorist would hand over the voucher to the doctor who attended him or his passenger, and the doctor would subsequently cash the voucher at the post office, while the motorist would purchase another. Unfortunately, "Hire-worthiness" proceeded to enlarge this simple proposition by raising the question whether a guinea would be sufficient recompense for treatment at a voluntary hospital, so that the discussion became discursive. Another writer revived the old proposal that every motorist should be compelled to insure against accidents, and that the insurance company should pay all medical fees. A third correspondent, Mr. Graham W. Thompson, was shocked to learn that motorists, as a class, habitually failed to pay for medical services, although in most cases medical charges were recouped up to a certain amount by the insurance companies. The facts of the matter seem to be as follows. The majority of motorists have motor policies. The majority of insurance companies include medical expenses in their policies without additional premium, and the driver may claim medical expenses for himself or for any passenger carried in the car. The amount allowed as medical expenses varies with different companies—from ten guineas to twenty, or even twenty-five guineas. Consequently in a large number of cases all the doctor could to a motor accident has to do is to send in a bill to the owner of the car and see that it is paid. His fee will be part of the claim made by the motorist on his insurance company. In a minority of cases the motorist may be uninsured. The question of compulsory insurance against injury sustained through motor vehicles has, we believe, been before the Ministry of Transport. Two arguments have been used against the proposal. The first is that compulsory insurance may tend to make the motorist less careful. The second, and perhaps more important, reason is that compulsory insurance for the motorist implies that someone must be compelled to insure him, however undesirable he may be. At present a company can refuse to renew a policy. It remains to be seen whether the arguments can be disposed of, and some scheme of insurance evolved which will neither force undesirables on the insurance companies nor necessitate the State undertaking insurance. This leads up to the consideration of the question of what should be done about injury to a third party—the worst case, when the motorist is neither driving nor is a passenger in the motor car. No insurance company takes cognizance of such a person unless he is able to establish legally a claim for damages against the motorist. There is no doubt that compen-

tion is sometimes paid without definite evidence of liability on the part of the motorist. The insurance companies may consider that, as a purely commercial proposition it may be cheaper to pay a reasonable amount than to defend a claim possibly unsuccessfully, and if successful find even the costs not recoverable. If however an action is brought against the driver, and the injured person fails to prove negligence, the doctor who renders aid must trust to the honour of the third party for his fees or else sue him. It seems that at present the only way in which the medical practitioner can be more certain of receiving remuneration for his services in motor accidents is by collecting his fee on the spot. The alternative of relying on insurance companies to pay the doctor direct whenever they admit liability for medical charges, might be raised with the companies but would probably be regarded by them as unacceptable.

### THE CONSTITUTIONAL FACTOR IN DISEASE.

No two men are exactly alike however similar they may appear to be. On the other hand a man may display some marked predilection, in which case we regard him as having a particular "constitution." As to what such a constitution is apart from its pathological manifestations, and how it varies is generally regarded as obscure. It suffices to know that a man with a "gouty constitution," though not suffering from gout is liable to do so. But it is worth while knowing what constitution itself is, and the subject has recently been discussed in our pages with all his customary lucidity by Dr. A. F. Hurst but a monograph published this year by Professor O. Naegele on the doctrine of constitution<sup>1</sup> is helpful although it takes a great many pages to show how recent advances in biological science have enlarged our knowledge of the subject. These advances have in the main been in the domains of botany and zoology, and Professor Naegele takes occasion to deplore the continued divorce of medicine from these sciences as hindering progress in this particular line. The possession of a distinctive constitution counts as a variation from the average, and the study of constitution involves a classification of the different types of variability and the discovery of their causes. Naegele expounds the subject on these lines. He in the first place separates spurious from true variation, many species reckoned apart under the Linnæan system of classification are now considered to be in reality groups of distinct species differing by comparatively small details formerly regarded as variations only. Small-pox affords an example of spurious variation. An epidemic of small-pox occurred in Canton Zurich in 1921 which was characterized by its extreme mildness; the symptoms though typical in the main, were slight and the mortality was almost nothing. Some constitutional variation, either in the patient or the virus, might have been named to account for the character of the epidemic. Investigation, however, revealed certain differences—in the blood cells, for example. The epidemic, Naegele thinks, started in Brazil, and travelled by way of the United States and England to Switzerland, retaining its characters under the varying conditions. For it he proposes yet another new name "varior nova," and thinks it is probably a species distinct from true small-pox, with its own virus that is as it may be—time alone will prove. Of true variation Naegele recognizes two classes—modification and mutation. Of the former, which is usually the result of some change in the external conditions, he finds a good example in the gradual change of physiognomy exhibited by Europeans after their settlement in America. Pathological thus affords many instances such as the immunity conferred by infective diseases. Mutation on the other hand is the sudden appearance of a new character in the

organism independent of external conditions and transmissible to the offspring. No better example could be given than that of the copper beech. In Switzerland and South Germany all trees showing this variation are derived from one which made its appearance for the first time in the year 1180 the colour being at the time attributed to the blood of a murdered knight. Of pathological examples Naegele gives a long list—leucophthalmia, Friedreich's disease, alkaptonuria, hyperostosis, Huntington's chorea, achondroplasia, multiple exostosis, and many others. In addition to these two types of true variation we have also to reckon with the innumerable particularities of form and constitution which may result from the mixture of races through hybridization and further the modifications of the organism arising from influences exerted directly on the ovum by germinal induction. As an example of the latter the thyroid gland is quoted. Observations made in goitrous districts were held to show that the thyroid glands of newborn children contained no colloid and this was erroneously supposed to be the normal condition. Apparently, however, all of these glands were abnormal, since by the adoption of a suitable iodine the rapid colloid was found present at birth. For many years the direct causes of disease have chiefly attracted attention to the comparative neglect of the study of constitution but the latter is again arousing interest and Professor Naegele in his monograph helps us to see how the subject should be approached.

### MYELOTOXIC SERUMS

Leucocytic serum has already been made the subject of study by Bunting, Huxer, Besredka, and others and more recently Gustaf Lindström has taken up their investigation with a view to obtaining a more potent serum and of testing their effect in cases of leukaemia in the human subject. His results are recorded in Supplement XXII of the *Acta Medica Scandinavica* in a paper written in English, and entitled "An experimental study of myelotoxic sera." He experimented with three different serums: (1) obtained by immunizing the pig with an extract of rabbit leucocytes, (2) by using washed leucocytes instead of an extract and (3) by immunizing rabbits with rabbit leucocytes. The potency increased in this order and with the size of the dose administered serum (1) was discarded as being too inactive. Small and moderate doses of serum (2) caused an immediate reduction of the leucocytes followed by a marked rise and a repetition of the dose produced a further fall followed by a rise. If now a large dose were given a more definite reduction occurred, the polymorphonuclear cells disappeared from the blood stream, the mononuclear cells remaining unaffected. A similar experiment with serum (3) showed a very powerful effect, the leucocytes normally 8000 per cubic millimetre being reduced to 50 here again the remaining cells were almost all polymorphonuclear. On 11 experiments were carried out to show the effect of repeated small doses. In the experiments on man an animal rabbit serum was employed. The antigen was obtained by allowing off blood from a leukaemic patient into a solution of sodium citrate the separated blood corpuscles were repeatedly centrifuged and washed and the leucocytes separated from the red cells by sedimentation. The leucocytes were then injected into rabbits intraperitoneally. Ten cases of myeloid leukaemia were operated upon and the technique results of the injections, symptoms and course of the disease are set out at length. The general theoretical results may be gathered from the following summaries. In Case 1 leukaemia was fully developed with moderate anaemia it was treated for about twenty months with some relief from x-rays and arsenic when this failed to produce any effect two serum injections were given, and were followed by a complete remission lasting several months, the patient, however,

<sup>1</sup> Naegele eine Konstitution und ihre Vererbung. Von O. Naegele. Berlin J. Springer 1926. (64 x 9 1/2 in. 118 1/2 figures. Pp. 466.)

died at the end of thirty-four months. Case II, after being under observation for three weeks, appeared to be almost moribund, an injection given at this time caused a marked remission, so that within a fortnight the patient was apparently well, the improvement was not maintained, and in spite of two further injections and treatment with x rays and arsenic, death occurred within three months. Case III was an ordinary case of leukaemia with good general condition, treated, apparently with some relief, with x rays and seven injections of serum during a period of over two years, towards the end there were signs of failing strength, but the general condition was good when the patient passed out of observation. Case IV was a typical example of leukaemia with good general condition, and was considerably benefited by a course of x rays, later, however, severe anaemia developed, three injections of serum failed to relieve, and death occurred within six months from the onset of treatment. Case V was only under observation for five months, but during that time considerable improvement under serum injections and x rays was noted. Case VI was an instance of leukaemia in a relatively favourable stage, considerable benefit followed x-ray treatment (and a single injection), and continued off and on for two years and a half, when its efficacy failed, the patient's condition became unsatisfactory, and a serum injection was followed by signs of intoxication and death. Case VII, with fully developed leukaemia, was under observation for nearly two years, a high leucocyte count was markedly reduced under the combined influence of serum and x rays, and with alternate courses of x rays and injections the condition remained stationary up to the time of discharge. Case VIII was that of a patient who was in a relatively good condition in April, but seriously worse in October, when two injections were given, the second of which caused death from intoxication. In Case IX the patient was not in a satisfactory condition, a serum injection rendered matters worse, and a second injection a week later caused death from intoxication. The serum used in Case X appears to have been too weak to produce any definite effect.

#### SARCOMA OF BONE

In 1920 the American College of Surgeons established a registry, under the charge of Dr. E. A. Codman, to make a collective study of the primary and malignant bone tumours, and to accumulate data whereby the pathology of these conditions might be defined and the value of various therapeutic measures estimated. The April issue of *Surgery, Gynecology, and Obstetrics*, which is the official journal of the American College of Surgeons, appears in two parts, the first of these is entirely devoted to a report by Dr. A. Kolodny, of Iowa University, of a personal study of 700 cases of bone sarcoma collected by the registry, together with a critical analysis of a classification suggested by the registry committee. Eight main groups of bone lesions were formed: (1) metastatic tumours primary in tissues other than bone, (2) periosteal fibrosarcoma, (3) benign and malignant osteogenic tumours, (4) inflammatory conditions, (5) benign giant-cell tumours, (6) benign and malignant angiomas, (7) Ewing's tumour, and (8) myeloma. Kolodny considers that it would be preferable to place all primary malignant bone tumours in four groups—namely, osteogenic sarcoma, Ewing's sarcoma, myeloma, and a small collection of unclassified sarcoma. He thinks that at present further subdivision of these four groups is unwise and that the proposed classification supplies sufficient aid in the recognition of the nature of any bony neoplasm, and the decision as to the extent of surgical intervention which may be required. The registry classification recognizes four anatomical types of osteogenic sarcoma—namely, the periosteal, the medullary and subperiosteal, the

scloerosing, and the telangiectatic. Codman doubts the advisability of this differentiation, but Ewing approves it on the ground that these types appear to differ from each other as regards their gross anatomy, histology, and clinical course. The main part of Kolodny's essay, however, consists of a close detailed examination of the four groups of malignant bone tumours defined by him. The term "osteogenic sarcoma," suggested by Ewing, includes mainly the lesions hitherto known as periosteal bone sarcoma, a description which ignores or denies the reputed origin of this growth from the precursors of the osteoblasts. Kolodny does not agree with the more recently expressed French view that these tumours are sarcomata of the cellular elements of the connective tissue in the bone and marrow. He also objects to basing subdivision of osteogenic sarcoma on the character of the malignant cells. He denies that round cells occur, and states that the cell most frequently encountered is small and spindle shaped, with a hyperchromatic nucleus. The chief morphological difference between osteogenic sarcoma and other malignant tumours is said to be its intercellular substance, which may be hyaline, osseoid, cartilaginous, myxomatous, or osseous. The most striking feature in the history and clinical course of Ewing's sarcoma is its appearance in young persons (less than 21 years old) as a consequence of trauma, so that osteomyelitis is suspected at first. Metastasis to other bones is common, and this, together with the response, usually rapid, to radiation, distinguishes it from osteogenic sarcoma, it, however, tends to recur, and gradually becomes refractory to further radiation. Myeloma is a bone-marrow tumour characterized by its incidence after the age of 40, multiplicity of involvement, rarity of pulmonary metastases and suitability for the ribs, sternum, vertebrae, and spine. It is seldom recognized before extreme skeletal involvement occurs, owing to its infrequency and the difficulty in early diagnosis. Local growths disappear rapidly under radiation, but no permanent recovery is recorded as having followed this treatment. The unclassified group includes angioendothelioma and extra-osteal sarcoma.

#### METABOLISM OF NERVES

The recent work of Downing, Gerard, and Hill, amplified by Gerard in the *Journal of Physiology*, dealing with metabolic changes accompanying the passage of impulses along peripheral nerve, has removed some of the mystery attached to the activity of nervous tissue. It has long been realized that the nerve is not an entirely passive agent in the transmission of an impulse, since an electrical change (action current) occurs in the nerve when it is stimulated, a nerve killed by asphyxia no longer conducts an impulse. Definite evidence of gaseous exchange, and particularly of any heat production as the result of activity, has proved exceedingly difficult to obtain. This is due largely to the difficulty of making small enough measurements. The work of Tishiro, Puikel, and others showed that peripheral nerve produced carbon dioxide, particularly during activity. By the use of very sensitive apparatus, in which the minute amount of heat produced by the nerve is magnified by a thermal relay, Gerard, Hill, and their co-workers have now been able to show that heat is indeed produced when a nervous impulse passes, and that during ten to fifteen minutes after the impulse has passed recovery of some description takes place, accompanied by a further and much larger heat production, this production is ten times as large. In order that the heat produced may be measurably great, it is necessary to stimulate many times a second, but by calculation it can be found that the amount of heat produced by one impulse is one millionth of a calorie per gram of nerve. We are thus faced with the extraordinary fact that the energy used by the contracting muscle is about one million times as

and it is that involved in the nervous impulse which causes the contraction. These observations tend to prove that, in some respects, the metabolism of nervous tissue is far more like that of other tissues than was at one time believed. For in times of careful examination of the oxygen uptake show that more oxygen is needed when the nerve is active than when it is at rest and in calculation it is found that the ordinary foodstuffs of the body—fat, protein and carbohydrate—are used by peripheral nerves. The utilization of glucose has also been demonstrated by chemical estimations. The facts we have endeavored to set out in this paragraph are highly technical but they have been noted because it seems likely that in the long run they will prove most important to the neurologist and they deal with the fundamental facts of nervous activity.

### LIFE EXTENSION IN AMERICA

That a periodic overhaul of the middle-aged is like the regular visit to the dentist a wise measure of preventive medicine is too obvious to need much argument. With the spirit of practical application which is characteristic of the New World this method of prolonging life has been put on a basis of mass production in America and in his address on "Lengthening of human life in retrospect and prospect," a documented argument in favour of the plan has been put forward by Irving Fisher, professor of economics at Yale. In 1914 the Life Extension Institute was established with the co-operation of the late General W. C. Clegg, ex-President Taft and others one of its objects being to "bring to the profit-making motive of the life insurance companies with the risk of lengthening human life." The experience of the Metropolitan Life Insurance Company in providing their clients with medical services was so remarkable that it evoked incredulity from its medical and statistical departments but careful investigation proved that after spending 60,000 dollars on the medical examination of 6,000 of their insured persons in six years the company had gained 120,000 dollars through the premiums of insured persons whose lives had been prolonged. In other words the company had made 100 per cent profit on the investment of 60,000 dollars. One of the chief points brought out by the Life Extension Institute was the enormous extent of unmet need, or, as it has been called, "silent sickness," thus, in an attempt to ascertain the influence of focal infections examination of many thousands of insured persons showed it to be so prevalent that it was not possible to obtain a group of non-infected persons as controls. The effect of the periodic examinations has been to stimulate and guide the half million examined in the paths of personal hygiene. For example, many found to be over weight had succeeded in correcting this by the next visit. The favourable results obtained by the Metropolitan Life have been confirmed by those of the Guardian Life and Postal Life Companies. That persons thus examined are thereby benefited is beyond doubt, but it is open to question whether or not the Life Extension Institute is the best machinery for making these examinations. No doubt it makes for consistency, but it lacks the knowledge of the individual which the regular medical attendant can alone supply.

### TRIAL BY BATTEL

The case of Abraham Thornton, heard in 1817 was remarkable in several respects, and led to an alteration of the law, a certain curious interest therefore attaches to the full report which has been published in the series of *Notable British Trials*. It was the last case in this

country in which a man who had previously been pronounced "Not guilty" by a jury was retried on the same charge, and it was the last in which the defence in such an appeal consisted of the assertion of the right to decide the question by personal combat. In addition the case has several peculiarities of interest and is a striking example of the ability of a jury, when directed by a sound judge, to disregard the violent prejudices of the countryside and to return a verdict in accordance with the evidence. Thornton was accused of rape and murder. He pleaded "Not guilty" to both charges but he admitted having had carnal knowledge of the deceased during a night spent in the fields with her after a rustic ball, but he alleged that it was with her consent. The evidence showed that she was seen well and cheerful at a later hour than any at which he could have been in her company. The girl's body was found in a deep pool into which she might by accident have slipped. According to ancient law the last of the "all-red" murdered person could lodge an appeal of murder within a year and a day of the completion of his felony by the death, and the plea of *autrefois acquit* or *autrefois convict* was no bar to the prosecuting or such an appeal. Unless the evidence of guilt was so overwhelming the accused person could demand trial *de novo*. This is what Thornton did. Drawing one of a pair of specially made fingerless gloves on his left hand he swung a fellow on the floor of the court, saying "Not guilty, and I am ready to defend the same with my sword." As Thornton was a strong man and the appellant a weakling the fight was not taken up and as there was no strong case against him he was allowed to plead his previous acquittal and was discharged. Popular feeling was, however, in his favour, and he was so persecuted that he thought it best to leave the country. Even this proved difficult according to *Arms Buntingham* (a little the other passengers in the ship *Indefatigable*, bound for New York, refused to go in the same vessel with him, but he managed to cross the Atlantic in another ship. In 1819 an Act of Parliament was passed abolishing trials by battle and appeals of murder and henceforward no one in this country could be tried a second time on a charge of which a jury had already acquitted him.

### AWARD OF THE LUCIAN HOWE MEDAL TO MR PRIESTLEY SMITH

The American Ophthalmological Society, the oldest in America at its origin in Quebec unanimously awarded the Lucian Howe Medal to Mr Priestley Smith and commissioned Dr W. H. Wilder to present it personally. On August 18th Dr Wilder visited Mr Priestley Smith at Birmingham and gave him the beautiful gold cross. He spent some time with our distinguished colleague, examining his wonderful injections of the eye of the ox, and studying the apparatus with which Mr Priestley Smith is carrying on his investigations regarding the circulation of the eye. The Lucian Howe Medal is awarded at infrequent intervals and has not been given four times. The first recipient was Dr Knapp of Vienna who introduced the use of cocaine into the surgery of the eye. The second was Professor Fuchs of Vienna and the third Dr Edward Jackson, one of the most inspiring teachers in America. We congratulate Mr Priestley Smith upon receiving the greatest honour which the American Ophthalmological Society can bestow.

As mentioned last week that Mr Alban Doran F.P.C.S., had recently undergone an operation for glaucoma and was a patient in St Bartholomew's Hospital. We regret now to have to announce that he died on August 23rd, he was in his 78th year.

## THE YEAR'S WORK OF THE METROPOLITAN ASYLUMS BOARD

THE Metropolitan Asylums Board is a body with large functions of which the general public has only a vague idea. Many people imagine from its title that its main work is in connexion with mental cases, whereas that is only one branch, and not the largest, of its activities. The Board serves an area of over 120 square miles and a population of 4,500,000. From its annual report for 1926-27, a volume of more than 400 pages, it appears that its own daily population of patients and other dependants and staff throughout the year averages about 28,000, and its property, exclusive of its nine casual wards, covers close upon 2,000 acres, or about the area of Richmond Park. It has 15 hospitals for cases of infectious disease, 10 institutions for tuberculosis, 6 for mental cases, 5 for sick or convalescent children, not to speak of its provision for the destitute poor or of its ambulance service, with 150 vehicles, which last year covered more than a million miles in the conveyance of the sick. The Board's medical and dispensing staff consists of 161 permanent and 13 temporary officers, and its nursing staff numbers 4,300. Its annual expenditure amounts to £2,213,000, of which £647,000 is spent on the care of imbeciles and the feeble-minded, and £888,000 on the treatment and control of infectious diseases.

### Infectious Diseases

The number of cases of infectious disease admitted to the Board's hospitals during 1926 was 30,403, higher by some 1,500 than the year before, but the number of deaths was smaller (1,036, as compared with 1,061). The following table has been extracted from the multitude of figures furnished.

Diseases	Remaining Jan 1926	Admissions, 1926	Discharged Recovered	Deaths 1926	Admissions 1925	Deaths 1925
Diphtheria	1902	10,527	9,854	510	9,247	458
Diphtheria (bacteriological)	130	1,108	1,074	14	1,004	4
Enteric fever	19	178	186	3	137	13
Measles	640	2,959	3,364	223	1,932	121
Scarlet fever	2,003	10,553	10,761	88	10,508	111
Whooping cough	53	775	448	59	1,483	219

The case mortality from diphtheria (4.88 per cent), and also from scarlet fever (0.8 per cent), was the lowest recorded. The question of the accommodation to be assigned respectively to measles and scarlet fever has been exercising the mind of the Board, and it has now been agreed that, in view of the higher mortality from measles (6.81 per cent) and its greater destructive effect on child life, the practice hitherto followed of always admitting scarlet fever cases in preference to measles should be given up, and that there should be a definite allocation of beds to these two diseases. So long as an ample margin of beds remains, cases of scarlet fever or of measles will be admitted as at present on doctors' certificates, but if a shortage of beds becomes imminent, any person desiring the admission of a case either of scarlet fever or measles will be referred to the medical officer of health, who will select the cases which in his opinion should be admitted, having regard to all the circumstances, especially the age and home conditions of the patient. The chief medical officer of the Infectious Hospitals Service, Dr F. H. Thomson, points out that although scarlet fever is now very mild in this and in many countries, it is not so in all. In Poland and Roumania the case mortality is over 10 per cent, and in Bulgaria over 18 per cent. Moreover, the history of scarlet fever shows that there have been great variations in respect to mortality. It is true that the case mortality in the hospitals of the Board has been under 5 per cent for more than thirty years, and 2 per cent or under for the last sixteen years, but scarlet fever, according to the accounts of Bietonneru in Franco and Graves in Ireland, was a mild disease in the early part of the nineteenth century, and so

remained for twenty-five years or more, after which it again assumed a grave form.

Of other diseases for which the Board makes provision in the infectious diseases hospitals, cerebrospinal fever accounted for only 17 admissions (9 deaths) in 1926, encephalitis lethargica for 21 admissions (7 deaths), poliomyelitis for 13 admissions (1 death), puerperal pyrexia and puerperal fever for 140 admissions (19 deaths), and zymotic enteritis for 12 admissions (2 deaths). There appears to be no reference to the experiment started in 1925 of concentrating puerperal fever patients in two or three hospitals and appointing a visiting obstetric consultant. In the last annual report the hope was expressed that after another year's work much information with regard to the infecting organisms and other matters might be elicited. Small-pox was the cause of only 5 admissions to the special hospitals in 1926, and there was 1 death. The infection was brought from Paris to London on two occasions during the year. The patient who died was a chamberman employed in a hotel at which one of the visitors from Paris had been staying. Two other members of the hotel staff were infected. During the last twenty years there have been only 340 admissions for small-pox, with 54 deaths, 23 of the deaths occurred in one year, 1922.

### Research and Pathological Work

We gave an account (*JOURNAL*, May 14th, 1927, p. 882) of the Board's southern group laboratory on the occasion of its opening by the Minister of Health. This laboratory is intended for research work into the primary causes of the diseases from which the inmates of the Board's institutions are suffering. All the institutions send to this laboratory their material for special investigations, and certain of them use it for routine work also. The number of bottles of diphtheria antitoxin supplied from the Board's antitoxin establishment during 1926 was 75,127, each bottle containing 4,000 units. The demand for serum culture tubes and throat swabs has largely exceeded that of any previous year.

An interesting account is given of an investigation carried out at Levensden Mental Hospital to elucidate the origin of an outbreak of typhoid fever which occurred last summer, with 24 cases and 6 deaths. It was arranged to examine the urine and faeces of every inmate and, as far as possible, every member of the staff, so as to identify any carriers. The 2,051 inmates were duly examined, and 10 new carriers, all males, were found, and the existence of one old carrier was confirmed. No carriers were found outside the wards in which typhoid fever had occurred, and in one of the wards affected no carrier could be found even on repeated examination. No female carriers were found at all, even in wards in which typhoid cases had occurred. Members of the staff to the number of 454 were examined—12 refusing—and no carrier was found among them.

The conclusion drawn by Dr J. E. McCartney and Dr W. C. Harvey from an examination of 234 diphtheria carriers is that the cause of the carrier state is a pathological process in the upper respiratory tract preventing the normal elimination of the bacilli during convalescence. The organism does not appear to be existing on living tissue, but on products of inflammatory reaction, and thus leads an extra-corporeal existence. The removal of the pathological condition when found will result in cure. Pure throat carriers are promptly treated by tonsillectomy.

Many contributions by officers of the Board appear in this section of the report. Dr W. Gunn reviews the present position of scarlet fever from the serological and clinical standpoints. Dr Alexander Joo gives a short survey of diphtheria prevention work in Edinburgh, where he formerly worked, and Dr W. Kelleher of similar work on the training ship *Hamouth*, where the Board trains boys for sea service. Dr H. Carter writes on the prophylactic value of alkaline therapy in scarlatinal nephritis. Dr J. V. Armstrong describes the use of the carbon arc in infectious fever practice, his most definite conclusion, after the treatment of 10 cases of whooping-cough, 5 of measles, and 4 of other complaints, is that there were hardly any striking successes to record, and that where definite improvement occurred it was difficult to say how much was due

to careful nursing and feeding and how much to specific light therapy. There was improvement in the general condition, but no rapid disappearance of the special symptoms of the disease.

#### Mental Diseases and Abnormalities

The Board has in its various hospitals and colonies provision for 10 000 mental cases. For a long time the only cases received were under the Lunacy Acts (chronic and harmless certified), but the number of these cases has declined in recent years, there has been an increase of cases certified under the Mental Deficiency Act, as well as of three groups of uncertified persons—namely, sane epileptics, feeble minded persons according to the definitions of the Local Government Board, and aged poor who by reason of mental infirmity need institutional care. Some anxiety is expressed by the Board at the number of feeble-minded persons who, after committing offences against the law, are remitted to the care of the Board from the police courts. The reception of these persons tends to accentuate the difficulties of managing the various branches of a certifying institution.

Another special class of mentally abnormal persons with which the Board has been concerned in recent years is that of persons suffering from the after-effects of encephalitis lethargica. The cases cut across the scheme of classification which the Board has adopted in mental cases, for some of them are certified under the Lunacy Acts, some under the Mental Deficiency Act, and others are not certified at all. Whatever their mode of entry, the practical effect is the addition of a number of particularly troublesome and turbulent individuals for whom the available accommodation is not very suitable. An experimental scheme under which the Board provided 100 beds at one of its institutions for the treatment of children so afflicted is the subject of a report after a year's work. Out of 133 cases in residence during the year, 12 have been discharged as much improved, 6 others in such a condition that further treatment was considered unlikely to improve them, 4 as unsuitable and 18 at the request of the parents, who desired to have their children home. It has been decided to continue the experiment for another year, and a stricter selection is to govern the admissions. Dr G. A. Borthwick contributes a very long and interesting report detailing his observations on the children, but beyond showing what an overwhelming amount of clinical material they present, and what problems of classification they bring in their train, he does not attempt to draw any conclusions. Dr T. H. Whittington, visiting oculist, states that the ocular signs commonly present at the onset and during the acute stage of the disease are comparatively rare during the post-encephalitic stage. What was most notable was the number of children with a tendency to divergence of the eyes.

There are detailed reports from each of the mental hospitals and a specially lengthy one from the Darent training colony, where there is a population of between 600 and 700, many of whom are being trained industrially.

#### Other Medical Work of the Board

The number of patients admitted to the Board's institutions for pulmonary tuberculosis during 1926 was 3 837. As the number of tuberculous sick is undoubtedly diminishing, and as there is not a corresponding diminution in the Board's figures, it is inferred that sufferers from this condition are resorting increasingly to hospital treatment, a circumstance particularly to be welcomed as the segregation of advanced cases of lung disease cannot but help to reduce gross infection of other members of the family. Of the 1,008 patients discharged from two sanatoriums for adults during the year, 72 per cent were classed as fit for full work or light work, and in 35 per cent the disease was described as quiescent. Dr Blith-Brooke has investigated the after-history of many patients treated in a sanatorium, and suggests that in the prognosis, while temperature charts and records of any hæmorrhage may be passed over quickly, pathological reports on the sputum should be carefully followed. His statistics show that diminution of the number of bacilli in the sputum during treatment is a favourable sign.

The expansion of St Mary's Hospital, Carshalton, by 350 beds for the accommodation of children suffering from subacute rheumatism, the later stages of acute rheumatism, rheumatic chorea, and rheumatic carditis, was determined upon a year ago, but the work which has to be done before a report can usefully be made is still considerable. At the same hospital 515 non-tuberculous orthopaedic cases were completed last year.

Among reports by officers and consultants is one from Mr Treacher Collins, stating that the establishment by the Board twenty-four years ago of a school at Swanley for the isolation of contagious eye disease has served to stamp out trachoma from the Poor Law schools of London. In 1911 the number of cases admitted from such schools was 103, last year there were only seven cases, five of which came from Poplar, where, in all probability, they had contracted the disease in connexion with the large outbreak of trachoma which occurred in the London County Council schools in that borough in 1925. The institutions of the Board received 3,928 sick children in 1926.

Other matters contained in the report include the inquiry into the conditions of the nursing service which has been proceeding under a committee of the Board. The Board complains of sweeping and general statements which have been made in support of the excellent movement for the provision of hostels for women. It has been said that hundreds of women tramp the streets of London nightly looking for shelter, a thing which, if true, would imply neglect of duty by the authorities. But in fact, during the last five years, a census of homeless women—taken usually during a night in February—has shown an average of only 27 and a maximum of 42 on the streets, while the number of vacant beds in common lodging houses on those nights was from 300 to 500. Any destitute person could be applying at the Board's night office, have been provided with a bed, either through the voluntary agencies or, as a last resort, in the casual ward.

## New Zealand.

[FROM OUR CORRESPONDENT]

#### RESEARCH WORK

FOLLOWING upon the epidemic of poliomyelitis in 1925, the New Zealand Branch of the British Medical Association induced the Government to undertake a research into the causes and prevention of this disease, the work being undertaken in the Otago Medical School. There have been delays in obtaining supplies of monkeys for experimentation, and difficulties of technique, but the research so far has served to confirm the conclusions of other observers, no definite result can be claimed as an addition to our knowledge of the disease. Another inquiry is being made at Dunedin into the nature of rheumatoid arthritis and allied rheumatic conditions. Laborious complement fixation tests as elaborated by certain investigators in America have been made in Dunedin, with the result that the claims of the workers in regard to the diagnosis and treatment of rheumatoid arthritis by serological methods have been sustained. In cancer research information is at present being obtained from the hospitals throughout the country and the results collected as a preliminary to further investigation. Tuberculosis in school children has been investigated by making tests of children in school in town and country. Positive reactors are again examined radiologically and by tuberculous speciality, and such children are sent to sanatoriums or followed up in their homes, advice being given to their parents.

#### GOITRE REMEDIES

Regulations issued by the Health Department, which come into force immediately, require that every bottle of goitre remedy shall bear a description of its active ingredients, and also a prominent warning that the remedy should not be taken save under the advice of a medical man. Since the public has learned of iodine treatment there is reason to believe that an increase has occurred in the number of cases of exophthalmic goitre, and these regulations are the outcome. The public has failed to

appreciate that, while a small amount of iodine is necessary for the proper functioning of the thyroid gland, large amounts cannot be taken without serious risk. The view of the Health Department is that iodized salt can safely be used for household purposes, and its use is authorized in breadmaking. The proportion of potassium iodide in this salt is 1 in 250,000. The primary purpose of this iodized salt is to prevent goitre from developing, though cases have occurred where goitre has lessened in size or even disappeared through its use. Seeing that regulations may be used to restrict the ill effects of proprietary and patent goitre cures, it would appear possible that more restrictions can be placed upon the indiscriminate sale of quick remedies in the interest of public health.

#### COST OF HOSPITALS

Hospital accommodation provided in New Zealand is, according to a statement made by the Director-General of Health, five beds per 1,000 of population, whereas the United Kingdom provides one bed per 1,000. Expenditure in New Zealand on hospitals is a serious drain on the finances of the country and is increasing, 73 per cent of the Revenue of all the hospital boards is derived from public funds, levies on local authorities, and subsidies contributed by the Government. The cost of hospital treatment averaged 15s 3d a head daily. The capitation charge averages 9s a day, but of this only 3s 6d is collected. The contributions from public funds, levies, and subsidies has risen from £443,000 in 1914-15 to £1,238,000 for 1925-26 and the expenditure per head of population from 7s 9d to 20s 5d. During this period of ten years no fewer than forty new hospitals have been opened, in addition to extensions of existing institutions. Mr. Love, director of charities in Victoria, a recent visitor to New Zealand, stated that the New Zealand system of hospital finance does not provide a sufficient check upon extravagance, and leads to waste and inefficiency.

## India.

#### LEPROSY IN INDIA

INDIA is one of the countries most favourably placed for the development of anti-leprosy work. Recently the Mission to Lepers has formulated a practical scheme for coping with the leper problem, and the British Empire Leprosy Relief Association has been actively engaged in stimulating interest in leprosy, as the result of an appeal of the Viceroy £150,000 has been subscribed for leprosy work. An additional research worker has been appointed at Calcutta, and it is hoped that within a short period well trained men of the assistant surgeon grade will be placed in all districts of Assam, Bengal, and the Central Provinces. One or two first-class practitioners are being allocated for leprosy work, and out-patient dispensaries are being started in all big cities. By linking this scheme with leprosy hospitals in the provinces when they are established a complete anti-leprosy service for the whole of India would be brought into being. As a preliminary to the organization of such a service a survey of the present institutions is the first essential, and this has been ably supplied by Dr. R. G. Cochrane, medical adviser to the Mission to Lepers, in a pamphlet of twenty-two pages, entitled *Leprosy in India: a Survey*,<sup>1</sup> which Sir Leonard Rogers, in a prefatory note, states should prove invaluable to the authorities of that country. The survey is the result of a visit to India in 1924 of a deputation sent by the Mission to Lepers. Dr. Cochrane accompanied this deputation, and a reference to its general report appeared in our issue of November 6th, 1926 (p. 845). The census of 1921 estimates the total number of lepers in India at 120,000, the returns, however, are known to be very unreliable, in many cases being sent in by ignorant villagers, and the author considers that if

the census figures were multiplied by eight or ten a better realization of the true number of lepers would be obtained. The pamphlet deals with each province separately, stating the number of lepers and their distribution in the area, the facilities for leprosy work, the clinics and other centres for educating manual men in the work, the hospitals, homes, and other institutions for the treatment of lepers, and their accommodation and organization, an excellent map, giving some of the above details at a glance, is appended. During the last decade much more precise practical knowledge of the stages of the disease has been attained. Three practically important types of case are now recognized: early cases, later infective cases, and chronic, uninfected, crippled nerve cases. Formerly there was no effective treatment for any stage, but it is now known that most of the first class lose all signs of the disease under treatment, and are thus prevented from going on to the infective stage, reduction of the prevalence of leprosy depends on the possibility of bringing these cases under treatment. For the later infective cases isolation is the essential measure. The crippled nerve patients could be sent to their homes without danger and with much saving of expense, this has been done in South Africa, but in India the patients are apt to be turned adrift by their relatives, and look to the various missions and Government asylums for relief, which, however, does nothing in this case to reduce the incidence of leprosy.

#### AMBULANCE AND HYGIENE TRAINING

The annual general meeting of the St. John Ambulance Association and the Indian Red Cross Society was held on June 24th, with the Viceroy in the chair. The annual report of the St. John Ambulance Association stated that 1,130 courses of instruction had been held at 316 stations, and that there had been an increase of about 42 per cent in the number of persons trained in first aid, as compared with 1925, gratifying progress had been made also in extending knowledge of home nursing, hygiene, and sanitation. Ambulance training was now being recognized more widely as a valuable part of education, in twelve provinces it had been introduced into the curriculum of the police force, and the Railway Board was considering a proposal to adopt it for its men. All-India ambulance competitions were becoming widely popular. The report of the Indian Red Cross Society contained a reference to the new scheme for supervising soldiers included out of the Indian Army. The society appealed for an increase in membership, it was mentioned that in 1926 it had only five thousand members, as compared with two and a half million in Japan. Provincial branches were invited to establish travelling dispensaries for service in rural areas. A striking illustration was given of the valuable work rendered to pilgrims by the opening of a fully equipped hospital at Haidar. This institution, with its forty beds, received a large number of patients, in it numerous operations were performed, and stretcher-bearers were provided for emergencies.

#### THE PARASITOLOGY OF PLAGUE

The account given by Dr. L. Fabian Hust in the *Ceylon Journal of Science* of the result of his researches in the City Microbiological Laboratory, Colombo, from 1912 to the present day has been reprinted in a volume.<sup>1</sup> Part I, with an introduction, deals with the transmission of plague by the blood-sucking ectoparasites of rats and the haemorrhagic and biting powers of rat fleas, their identification and distribution, Part II, with the flea species factor and other considerations governing the spread of plague, regional studies in the parasitology of this disease, and the relation of parasitology to plague prevention. At the time when Glen Liston and the British Indian Plague Commission (1905-12) established the rat flea theory of transmission on a firm basis, many striking anomalies in the spread of plague in India, including the causes of the comparative

<sup>1</sup> *Leprosy in India: a Survey*. By Robert G. Cochrane. M.B. Ch.B., M.P.C.I. (Lond.) D.T.M. and H. London: World Dominion Press, 1927 (6 x 9 1/2 pp. 22, 1 map, 2s.).

<sup>1</sup> *Researches on the Parasitology of Plague*. By L. Fabian Hust. M.D. (Lond.) Colombo Municipality Department of Health, Colombo, 1927. London: The Times of Ceylon Co., Ltd. 1927 (Gr. 4to pp. 155, illustrated).

fic dom of large areas, remained unexplained. Whether all species of flea readily biting rats were equally efficient as vectors of plague between rat and rat was unknown and little attention had been paid to the relative possibility of the various species of rat fleas for the spread of epidemic as opposed to epidemic plague. To the elucidation of such problems Hirst has devoted himself, and his general conclusions may be quoted.

The spread of bubonic plague among rats throughout the world primarily depends on the [Xenopsylla] flea population of the invaded region. The population is a function of both the flea index and the average number of fleas per rat and the rat population commonly gauged by rats trapped per 100 traps.

The magnitude of the flea index depends primarily upon the effect of climate on flea reproduction and secondarily upon the nature and contents of the premises in which the flea is reproduced. The rat population depends primarily upon the available food supply.

The constant relation between flea distribution, plague prevalence among rats and human beings, and the distribution of imported grain is emphasized and the practical issue involved by full recognition of these discoveries become obvious. The study of the history of the spread of plague in Colombo is associated with the history of a particular flea as interesting reading as the history of the migrations of a human race.

#### PUBLIC HEALTH IN AGRA AND OUDH

In the United Provinces of Agra and Oudh there was during 1925 a satisfactory decline in all diseases and causes of death except smallpox and injuries. Lieut. Colonel C. L. Dunn, I.M.S., director of public health in the United Provinces, states in his annual report that no regular smallpox hospitals exist, patients being treated in temporary buildings or general hospitals for infectious cases. It has often been very difficult to isolate the patients satisfactorily, owing to the lack of compulsory measures, and much still remains to be done as regards vaccination. He comments also on the difficulty of obtaining from the district authorities notifications of primary outbreaks of cholera without considerable delay. In some cases the epidemic had actually subsided before information was received of its having begun. The Indian Research Fund Association during the year made a financial grant towards cholera research. Antimalarial activities were intensified in various places, particularly in the Sarai Canal area where a complete system of drainage has been constructed despite considerable difficulty, the results of quinine prophylaxis were particularly good. Plague outbreaks continued to be mild on the whole though the south-eastern and some western districts experienced severe epidemics. Prophylactic inoculation was usually welcomed by the inhabitants, and no difficulty was experienced in securing the vaccination of infected villages. The plague staff consisted of four special health officers and forty-two travelling dispensaries. Active research was carried on into the transmission of this disease by the two chief vectors of fleas encountered. It is suggested that the present mildness of epidemics may be an indication of a decline of plague in severe epidemic form. The thirty-six public health travelling dispensaries which are engaged in general medical work are becoming increasingly popular and proved most valuable in the control of epidemics of various kinds during the year under review. Over 240,000 patients were treated by them, and more than 4,000 operations were performed. For special emergencies twelve additional travelling dispensaries were temporarily mobilized and treated some 12,000 patients. Education in the prevention of disease continued energetically, and was a useful feature of the work of these dispensaries. A hygiene publicity bureau was established in the province and extensive educational tours were made for the purpose of lanterns being used. In response to the growing public demand for more facilities of this kind additional lanterns and more booklets and posters are to be provided. Grants in aid were received from the Government, various district and municipal authorities, and the Indian Red Cross Society.

## England and Wales.

### SOME PROBLEMS OF MENTAL HOSPITAL ADMINISTRATION

INCREASE in the number of patients admitted during 1926 to the Stafford Mental Hospital has compelled attention to the growing difficulty of accommodation. It has been found necessary to devote the twenty beds in the isolation hospital to convalescent male patients, but it is obvious that should an epidemic occur the necessary accommodation of this building would cause very severe congestion in the main ward. An annex containing ten beds for tuberculous male patients, nearing completion, but additional accommodation for uncomplicated mental cases will be required at an early date. Dr. B. H. Shaw, medical superintendent of the hospital in his annual report for the year ending March 31st, 1927 suggests that relief of overcrowding can be effected only by making use of the vacant accommodation in Poor Law institutions for the reception of certain cases, and by special provision for idiots, imbeciles and other patients with definite mental deficiencies becoming manifest at an early age and requiring institutional treatment. He considers that to associate together the imbecile type and persons suffering from simple mental breakdown is most undesirable. Among other objections to the treatment of cases of early mental disorders in general hospitals Dr. Shaw includes the fact that the conditions are usually situated in industrial centres where there is little possibility of securing the quiet outdoor environment and special amenities necessary for the successful treatment of mental breakdown. Moreover, the training of general hospital nurses does not meet the requirements in dealing with early mental cases, since the rigid discipline necessary in dealing with physical illness is out of place in the treatment of the extreme temperamental sensitiveness associated with mental disorder. Dr. Shaw considers that the establishment of clinics for early cases is unlikely to have very much effect unless arrangements are made to remove the patients from their home surroundings. He is driven to the conclusion that any measures to relieve the existing congestion, other than the erection of additional buildings, can only be considered palliative, he mentions that the erection of a separate building for acute and newly admitted cases has been prevented hitherto by financial considerations. The question of 'boarding out' patients has been considered and this policy may have to be adopted, though, in Dr. Shaw's opinion it has little to commend it except expediency.

### THE ROYAL VICTORIA INFIRMARY, NEWCASTLE-UPON-TYNE

DURING 1926 the number of in-patients admitted to the Royal Victoria Infirmary, Newcastle-upon-Tyne (13,922), established a record for this institution additions being made to the beds in the Infirmary and thirty beds being provided in the Innes Hopkins Home at Ryton, which was taken over as an auxiliary hospital. On many occasions extra beds had to be placed in the wards. In the annual report of this institution for 1926 it is stated that much of this expansion was rendered necessary by motor accidents, which reached the figure of 980, 432 persons had to be admitted as in-patients. These figures are double those of the previous year. 54 patients died, equivalent to a mortality due to motor accidents of over one a week. Since many of these patients were in a very grave condition on admission preference had to be given them over those on the waiting list, the number upon which at the end of the year was 2,100. During 1926 accidents of all kinds were responsible for the admission of 2,119 patients, as compared with 2,036 in the previous year and this in spite of the closure of many collieries and much diminished employment in various other industries. The Infirmary committee is therefore compelled to give serious consideration to the problems created by these conditions. Moreover, in the out-patient departments there was an increase of 8,000 new cases, and the number of operations rose from 13,225 in 1925 to 14,409 in 1926. The general expenditure of the Infirmary exceeded the income by nearly £10,000. The fact that voluntary subscriptions declined by

only £11,703 is considered to be a matter for congratulation in view of the wide spread distress consequent on the industrial situation. There was also a reduction in the contributions by patients but it is believed that when employment becomes better a great increase in the donations may be expected. Promises have already been received to the effect that an attempt will be made during the current year to compensate in some measure for the deficiency of 1926.

#### ST BARTHOLOMEW'S HOSPITAL

St Bartholomew's Hospital is in the happy and unusual position of having an income in excess of its expenditure. The explanation is that it receives over £120,000 from invested property. It has in hand a scheme for erecting an operation theatre block, a new surgical ward block, and reception rooms for nurses at a cost of about £200,000. It now has 688 beds, and 666 were in constant use during the past year, when £18,000 was spent on renewals and repairs, it paid £4,800 in rates and taxes. It received 2,972 persons suffering from street accidents or illness brought to it by motor ambulances belonging to the Corporation of the City of London or the London County Council.

## Ireland.

#### PROMOTION OF MEDICAL OFFICERS

ARISING out of representations made on behalf of the profession to the Minister for Local Government and Public Health (Free State) with regard to Section 5 of the Local Authorities (Officers and Employees) Act, 1926, in connexion with the promotion of medical officers by boards of health the Minister has addressed an important circular letter to each local authority. The Minister's approval for the transfer or promotion of an existing medical officer is necessary under Section 5 of the Act and he clearly defines the conditions to be fulfilled by the local authorities in order to get his approval of appointments made by them by way of promotion.

The Departmental Secretary states that he is directed by the Minister for Local Government and Public Health to refer to Section 5 of the Local Authorities (Officers and Employees) Act, 1926, under which, subject to the sanction of the Minister, local authorities are empowered to make appointments to offices to which the Act applies (as defined in Section 2 thereof) from amongst persons holding pensionable offices under local authorities or in receipt of superannuation allowances from local authorities and who are performing or had performed duties the same as or similar to those of the office to which it may be proposed to make an appointment. It is stated that the Minister has had under consideration the procedure which should be followed by him in giving or withholding his sanction to a local authority proceeding to make an appointment under the section, and has decided that in future he will not give his sanction to the making of an appointment thereunder unless he is satisfied that a suitable and properly qualified person is available for appointment. In giving or withholding his sanction to the making of an appointment under the section, the Minister will be influenced solely by the merits of the case. Accordingly a local authority should in the interests of efficient local administration carefully consider the qualifications, training, experience, age, character and length of service of the persons available for appointment. Due weight should be given, other things being equal, to seniority, since one of the objects of the section is to facilitate the promotion of existing officers of local authorities on grounds of ability and length of service. In future therefore an application for the Minister's sanction should be accompanied by a clear statement of the grounds on which the application is made.

#### TUBERCULOSIS IN BELFAST

In his annual report for the year ending December 31st, 1926, Dr Andrew Trimble, chief tuberculosis officer for the county borough of Belfast, states that the attendance at the tuberculosis institutes for examination and treatment numbered 34,040. Of these, 1,904 were new patients, among whom 1,054 were diagnosed as tuberculous, 115 as "suspect," and 856 definitely non-tuberculous, 121 having been transferred from the "suspect" list of 1925. The report showed that 64 fewer patients were found to be suffering from or suspected of tuberculosis than during the previous year, this decrease, though small, is gratifying in view of the prevailing industrial distress and housing shortage. In addition to the above, 220 old patients, unable to travel, were re-examined in their houses, and 44 at the

Belfast Infirmary, 822 patients on domiciliary treatment were also examined, of whom 254 were apparently cured, no signs of active disease being found. If this result can be attained under domiciliary treatment, with its attendant disadvantages of overcrowding and bad hygienic arrangements, how much more, it is asked, could be accomplished if housing and social conditions were bettered, and patients could and would carry out their instructions to greater advantage? The ratio of pulmonary tuberculosis to other forms of the disease varies only slightly from year to year, about 71 per cent of cases being pulmonary, the incidence among males and females, calculated on the ratio of their respective numbers in the population, was almost equal, in former years females were the greater sufferers. Dr Trimble draws attention to the social conditions favouring infection by contact, and notes that, after making every allowance for inadequate housing, unemployment, and distress, many patients still have to share bed rooms and beds with other members of their families, only 14.5 per cent of patients occupy single beds. The number of x-ray films exposed during the year was 225, and valuable work has been done in the dental department. The sputum was examined in 902 instances, and 238 other bacteriological examinations were made. Dr Trimble states that from an investigation of 1,691 cases of non-pulmonary tuberculosis it was found that 43 per cent had been in association with pulmonary forms, he therefore considers it fair to assume that the 57 per cent who had no such association were infected through milk. He draws attention to the unsatisfactory state of the local milk supply and notes that, of 17 samples found to contain tubercle bacilli, 15 were from milk produced outside the city boundary, and therefore outside the jurisdiction of the local authority. He advocates one governmental central authority for milk inspection and also an extension of the regulation (in force in Great Britain, but not yet applicable to Northern Ireland) which prohibits persons suffering from pulmonary tuberculosis from handling milk for sale. In addition to the ordinary methods of diagnosis and treatment by hygienic measures and medicines, the Belfast Insurance Committee gave a sum of £80 for the purchase of an interferometer, to investigate the possibility of earlier diagnosis. The use of sanocycin has been continued, Dr Trimble is of the opinion that this drug marks a distinct therapeutic advance in certain types of cases. Towards the end of the year a trial of Ruppel's serum was begun, but no opinion on its efficacy can yet be expressed. Lectures given during the year obtained wide circulation in the press. As to the value of the tuberculosis scheme in Belfast, Dr Trimble says that the death rate from all forms of the disease, as compared with 1914, has fallen by 38.5 per cent, and that of the pulmonary forms by 34 per cent. In the five years 1914-18 the number of children under 10 years dying from tuberculosis was 298, while in the five years 1922-26 the number was 109, a reduction of 63.5 per cent. It should be thought that this result is due to a general improvement in the health of the people, he states that, whereas the general death rate, exclusive of tuberculosis, has fallen 20 per cent between the five-year period mentioned, the death rate from tuberculosis has fallen 39 per cent—that is, almost twice as rapidly—and for these reasons Dr Trimble feels justified in saying that the scheme has, up to the present, fulfilled its object.

#### VITAL STATISTICS FOR NORTHERN IRELAND

During the quarter ending June 30th, 1927, 7,298 births were registered in the twenty-seven superintendent registrars' districts in Northern Ireland, this was equivalent to an annual birth rate of 23.3 per 1,000 of the estimated population, as compared with the corresponding figures of 17.6 for England and Wales, and 20.6 for Scotland. The deaths registered during the quarter numbered 4,979, representing an annual rate of 15.9 per 1,000, as compared with 11.0 for England and Wales, and 12.9 for Scotland. The birth rate was 0.4 below the rate for the corresponding quarter of 1926, and 1.2 below the average rate for the second quarters of the ten years 1917-26. The death rate was 0.7 below the rate for the corresponding quarter of 1926, and 1.3 below the average for the second quarters of the previous ten years. Of the 4,979 deaths registered,

914 in 1884, occurred in public institutions, and 445 or 88 per cent. were uncertified, there having been neither a medical attendant during the last illness nor an inquest held by a coroner. The number of successful primary vaccinations registered in Northern Ireland in the quarter under review was 7,128. The birth rate for county boroughs and urban districts, which contain more than one half of the total population of Northern Ireland, was 25.8 per 1,000 of the population, the birth rate for the remainder of Northern Ireland was 20.6 per 1,000. The mortality in the county boroughs and urban districts was 14.1 per 1,000 of the population, and the corresponding rate for the remainder of Northern Ireland was 17.7 per 1,000. The urban mortality from the principal epidemic diseases recorded during the quarter was equivalent to an annual rate of 0.8 per 1,000 of the population, the death rate from these diseases for the remainder of Northern Ireland being 0.4 per 1,000.

## Scotland.

### A TRIAL FOR MURDER IN 1728

At the annual meeting of the Forfarshire Medical Association the presidential address was delivered by Dr R. C. Buist of Dundee, who took for his subject 'A trial for murder in Forfarshire nearly two hundred years ago.' In 1728, Dr Buist said, the provost of Forfar was, like Provost Lawson of today, a doctor. He was the first medical witness in a trial for murder which must have attracted a great deal of attention, for the dead man was Lord Strathmore and the persons concerned in the trial which led to his death were all local notabilities. On May 9th a daughter of Carnegie of Lour had been buried and after the funeral the gentlemen, having dined and drunk a good deal of wine, adjourned to an inn in Forfar, where they drank more wine. Lord Strathmore then went to call on Lady Auchterhouse, widow of a relative, and sister of Carnegie of Finhaven who followed him to her home, accompanied by Lyon of Bridgeton. An altercation took place about a proposed matrimonial alliance, Lyon became violent and hammered Carnegie's head on the table. The dispute was continued in the street and Lyon upset Carnegie into the gutter, which was a very muddy gutter, and filled his top boots. Carnegie was helped out and saving that 'his was unbearable' drew his sword and made after Lyon. The Earl of Strathmore interposed, Carnegie lunged forward, was impaled on the sword and died in two days. Three months later Carnegie was tried for murder. A Dr John Kinloch of Dundee who had graduated M.D. at Rheims in 1712 and had studied at Leyden, testified that at the funeral the two contestants had been quite courteous to each other, supporting the plea of the defence that the tragedy was not purposeful and that there was no element of malice in it. William Douglas, late provost and a chirurgion-apothecary in Forfar, gave evidence that he had "pinned" the earl, and had advised that physicians should be summoned from Dundee. He noticed that the momentum had been pulled through the wound and deduced therefrom a nick in the sword such a nick was found in Carnegie's weapon. Thomas Crichton, a surgeon-apothecary in Dundee, said that the sword had entered the front of the abdomen and passed through the back, the earl had expressed the opinion that the thrust was not intended for him. It may be noted in passing that in the rising of 1745 Crichton was surgeon to the second battalion of Lord Ogilvie's regiment, and passed the rest of his life on his brother's estate at Ruthven. A Dr John Wedderburn of Dundee, who had studied at Leyden in 1700 and graduated M.D. of Utrecht in 1703, testified that he had been present at the necropsy on the earl and that the sword had passed through the caul, the gut-colon and the plexus m. entericus. A Dr Charles Fotheringham of Dundee, who also had studied at Leyden in 1722 and graduated M.D. at St Andrews three years later, agreed with the evidence of Thomas Crichton. Dr Buist stated that the jury, by a plurality of votes, brought in a verdict of 'not guilty.' At the dinner after the meeting the president was supported by the Earl of Strathmore and

Dr J. Tawson provost of Forfar. The president proposed the toast of 'The County of Forfar,' and Lord Strathmore responded. The toast of 'The Cuests' was proposed by Dr T. P. Dewar, who had been elected to succeed Dr Buist as president for 1927-28, and acknowledged by Provost Lawson. The toast of 'The Forfarshire Medical Association' was proposed by the Rev. W. G. Donaldson, parish minister of Forfar, and Dr J. Cable replied.

## Correspondence.

### AN OPERATING THEATRE OUTFIT

Sir.—Opinions seem divergent as to how the ideal operating room should be constituted. Some proclaim the advantage derivable from artificial ventilation and calefaction, while others, including myself, prefer a theatre which receives a share of any sun that is going as they consider any room uninhabitable—a tubercle haunt—if its atmosphere is denied disinfection by sun rays, and reject artificial ventilation in favour of ordinary fresh air through open window, with some windows at the level of ceiling to eliminate vitiated air.

I am in complete accord with Mr. Rowlands and Mr. Hamilton Whiteford as to the irrational practice of working in a stifling atmosphere, detrimental alike to patient and operator. Experience derived from the great war accentuates the necessity to adopt measures to keep the patient warm during operation—this cannot be effected by a superheated atmosphere and a cold slab, but by some special heating of the operating table for which fixation of an electric resistance in the latter has been found extremely convenient and efficacious, in combination with an insulating mattress (covered by rubber) to prevent burn the body of the patient above and below the operating field should be kept warm by wrapping in wool with mackintosh superimposed—all fixed in position by strong safety pins.

Keeping a patient warm during operation is analogous to keeping warm in bed during winter—namely, plenty of covering with an open window to provide the fit and fresh feeling in the morning. Possibly this may be a personal idiosyncrasy, and open to correction by those who not only sleep with window shut, but cover mouth, nose, and the rest beneath the same sheets. This is especially apropos to the context as it simulates the condition of the patient under anaesthesia in a close room, asphyxiated in exhalation and gas.

In my theatre a free supply of fresh air is provided during hot weather by four large lateral windows which are kept wide open and two long narrow windows level with the ceiling which are open in all seasons. Currents of air which might affect exposed viscera are avoided by closing the corresponding lateral windows.

From the beginning (1894) it has been my custom to wear clothing which will afford the light and airy feeling during operation so desirable, short hair and nails and healthy, clean teeth help to obviate the necessity for a beardgear rivaling the immaculate combination of a Turkish madonna and a French clerk, not to add "plus fours" a light sterilized gown over a light mackintosh apron comprise the outfit.

While a believer in the employment of sterilized rubber gloves by assistants and dressers—and personally in optic cases—I should as soon think, before entering the drawing-room after a post-prandial wash of hands, of confiding the adjustment of buttons to gloved fingers, as to trust the latter to separate adhesions—out of sight—in an abdomen, or palpating, for a foreign body or tumour in the brain. Physiologists who have made various studies of organic tactile sense declare that even with the interposition of the most delicate foreign membrane between living parts acuity of perception becomes diminished, and stimulation to cellular response appreciably lessened.

Sand-bags and sand-pillows are employed to secure the patient's position, except for the Trendelenburg which is effected by means of a Dwyer table, with similar artificial heating in its central compartment.

<sup>1</sup> *Annals of Surgery*, January 1923, author.

<sup>2</sup> *BRITISH MEDICAL JOURNAL*, February 24, 1922, author.

For use on dull days and at night two 1,000-candle-power electric lamps—one over each table—are suspended from the ceiling. During winter or other cold period three calefacturs standing out from the wall heat the interior. The walls of the theatre are lined with stucco, and are rounded off at the level of floor and ceiling. They are painted annually—the lower half reseda green and the upper section, and ceiling, white—I am, etc.,

Buenos Aires, May 31st

JOHN O'CONNOR, K B E, M D

### "PEINE FORTE ET DURE"

SIR—The very fascinating article by Mr R R James in your issue of August 6th (p 230), entitled "Hanged, Drawn, and Quartered," raises many points of considerable interest. Torture has not been recognized by the common law of England, though it was carried out frequently in the Middle Ages. But there was one form which could be ordered by a judge, not to obtain evidence, but to compel a prisoner who "stood mute" to plead, or to punish him if he did not do so. Before the infliction of this form, the *peine forte et dure*, the prisoner was warned three times, and the dreadful penalty explained to him, he was then given a few hours to think the matter over. If the accused were still obdurate, the judgement of perjury was pronounced and carried out. The sentence was not left to the discretion of the judge, for he was, by law, compelled to pass it in cases where an accused person refused to plead. The wording of the terrible judgement was as follows:

"That you be taken back to the prison whence you came, to a low dungeon into which no light can enter that you be laid on your back on the bare floor with a cloth round your loins, but elsewhere naked that there be set upon your body a weight of iron as great as you can bear and greater that you have no sustenance save on the first day three morsels of the coarsest bread on the second day three draughts of stagnant water from the pool nearest to the prison door on the third day again three morsels of bread as before and such water alternately from day to day till you die."

There are many recorded instances in which this was carried out. One of the most remarkable is that of Major Stringer. In 1685 he was accused of the murder of his brother-in-law. He refused to plead, and this meant he could not be tried, and therefore his lands would be preserved for his heirs. He was sent to endure the *peine forte et dure*. Major Stringer was pressed to death, the executioners mercifully hastening the ending out of the sentence by adding the weight of their own bodies to the mass of iron, and thus saving the prisoner the rest of the tortoise.

The barbarous law was repealed in the reign of George III. Before that reign many offences were punishable by hanging—for instance, arson, rape, forgery, house breaking, and horse-stealing. Juries, moved by feelings of pity, over and over again refused to convict even in the most obvious cases, for they considered the punishment too terrible for the offence committed. In 1808 the law was so altered that murder and treason were practically the only offences for which the death penalty remained.

Previous to the passing of the Acts in the reign of George III public opinion allowed even young children to be executed. In 1791 a boy of 8 who had set fire to a barn was hanged. It was only in 1908, when the Children Act became law, that the death penalty was abolished for young people under 16.

Mr James refers to death by boiling. At one time this was the punishment for poisoning, and was in a few instances actually carried out, but the law was repealed in the reign of Edward VI. There are a very great number of points in connexion with this question of brutal punishment to which I should like to refer, but I am afraid I have already occupied too much space—I am, etc.,

### ORTHOPAEDIC TREATMENT

SIR,—In view of the somewhat pessimistic tone of the discussion on orthopaedic treatment at the last Representative Meeting (reported in your SUPPLEMENT of July 23rd, 1927, p 43) it may interest your readers to hear of the lines on which the Bath, Somerset, and Wilts orthopaedic

scheme is organized, as the conditions appear to meet admirably the recommendations of the British Medical Association Council.

In the area there are, in addition to the Bath City Clinic, ten major (surgeon's) county clinics, as well as various minor ones (attended by orthopaedic sister only). At these clinics no case is seen except on the recommendation of either the family doctor or the school doctor, in the latter case the family doctor's permission is first obtained, and he is invited to attend the clinic. A number of local practitioners avail themselves of this invitation and always receive a warm welcome. Some are regular attendants and even kindly transport cases to the clinics, where they often stay to watch the routine working, as well as to see the treatment of their own cases. Unfortunately the demands on the busy practitioner's time do not allow him to stay sufficiently long to gain a thorough knowledge of the working of a clinic, nor do as many practitioners make the effort to attend as the clinic authorities would wish.

In this area a great deal of work in the clinics is done by detachments of V A D nurses, and among such voluntary workers the wives of local practitioners play a conspicuous part, which provides another link between the doctors and the clinics.

Narrowness of outlook ought not to be a danger in this area, as the surgeon in charge of the clinics, though now restricting practice to orthopaedic consulting work, had previously many years' training in general surgery and at one time had a large general practice.

Patients found to require dental, ophthalmic, or throat treatment are referred to local special clinics, provided that the parent declines to consult the family doctor. Other non-orthopaedic conditions are referred to general practitioners. It would be anything but kindness to force upon the family doctor the unremunerative type of case which forms the majority at the rural clinics—for example, the numerous progeny of an ill-paid farm labourer. As many neurological cases reach the clinics, an invitation is given from time to time to the neurologist attached to the central hospital to see groups of these at the various clinics.

As regards the staffing of the central hospital the beds are shared equally by two general surgeons and the orthopaedic surgeon, who runs the clinics, while the neurologist physician, above referred to, is also attached to it.

Finally, as to general principles the orthopaedic cases which represent the greatest cost in time and money are the very ones that general practitioners and even the local surgeons have been coping with for years, the initial lack of success being largely due to administrative and financial difficulties, which would never have been overcome but for the co-operation of the public health authorities.

As long as the conditions of general practice remain what they have been in the past the probability is remote that the general practitioner would have more success with the cases in the future than he has had hitherto. What these obstacles are has been pointed out in many recent speeches and articles—I am, etc.,

### TONSILS AND RHEUMATISM

SIR,—With regard to Sir George Newman's recent dictum that enlarged or inflamed tonsils are a cause (or the cause?) of rheumatism in children, may I, in all diffidence but with a past of thirty years' constant experience of clinical work, make a conflicting suggestion?

Is it not a fact that the enlarged tonsils may be, not a cause, but in many cases a result of rheumatism? I think it is now fairly well established that many, if not most, cases of follicular tonsillitis are rheumatic in origin. That, I take it, means that the rheumatism was the cause of the tonsillitis, not vice versa.

I have had the chance of observing a number of cases in which, after the tonsils had been removed, the rheumatism has persisted. Many other cases of rheumatism in children I have observed where there never were any sign or symptoms of tonsillitis, at any time.

The tonsils, surely, are only aggregated masses of adenoid

the use, and only become permanent foci of infection when materials of tractive to the pharynx, and when there is fibrous induration.

All the adenoid tissue in the nasopharynx is a possible cause of infection, even if we remove the tonsils, but does not all this tissue collect and kill many times more poisons (whether germs or otherwise) than it passes on.

The appendix is now having some justice done to it by pathologists. How many appendices have been successfully and brilliantly removed (in a healthy condition) for a flapping flaccid circum? Endocrine glands are coming into their own even the epiphysis and hypophysis cerebri.

When I was a house-surgeon we were taught to remove tuberculous cervical glands early. More recently, I believe especially by the practice and teaching of the late Treves at Margate, it has been found that general constitutional treatment without removal of glands (except when they suppurate) gives much better results.

I think it is a fact well established by clinical observation that enlarged tonsils where there is a fairly good airway and not much if any permanent fibrous change will often yield to general medical and hygienic treatment—especially, as regards drugs, to a mixture containing iodine. In my small experience I have used an alkaline potash solution containing tincture of iodine which I believe, has a local effect and changing in the stomach to free iodine, iodide, and iodate, has a very important general effect.

What I wish to maintain is that (where there is a good airway, or nose breathing can be maintained or developed) removal of a bit or two of adenoid tissue (the tonsils) which are surrounded by masses of adenoid tissue throughout the whole nasopharynx is in many cases at least, not radical or curative. May I add what seems to me one of the most important single points in this subject—that is, that rheumatism in children so often takes its first or for a long time, merely the form of "growing pains," which may very readily be overlooked—I am, etc.,

G D PARKER  
Fleckwell Hill Bucks Aug 18

### LATE RESULTS OF TONSIL AND ADENOID OPERATIONS

SIR,—A great deal is written on the technique of this operation, and figures are quoted—often running into thousands—of patients on whom it has been performed. It is always tacitly assumed that if the operation is satisfactorily performed (which goes without saying if the particular technique described is followed) the patient will be very much benefited but in clinical practice, where we see our patients over a number of years the result is not always so gratifying. It is one thing to be able to demonstrate the intact capsule of a tonsil which has been removed but another thing to demonstrate patients before and after the operation. My own figures are too small to be worthy of quoting, but I have noticed the following end results:

1. Marked improvement of general health and rapid growth following the operation.

2. No particular effect. This is sometimes very disappointing. For example a boy aged 5 was a mouth breather rather deaf, eunited thin and had the adenoid facies, the tonsils were constantly studded with white creamy exudate. After a course of gargles and throat painting I enucleated the tonsil and removed the adenoids. He developed acute otitis media for which I incised the drum. A year later the boy is still rather stunted rather deaf but a nose breather and is still very thin.

3. Child made very nervous. I have known this happen twice. In one case a little girl aged 5 frequently had white spots on her tonsils and a furred tongue and was generally out of sorts. I enucleated the tonsils after which she became very nervous and for more than a year was subject to bad dreams and night terrors after that I lost sight of her as the parents took her to another doctor.

Complications sometimes occur, of which I suppose, otitis media is the chief. I have been fortunate in only meeting with it once in private, but in hospital it used to be fairly frequent.

I had one case of a child aged 4, who had been operated on in London. She must I think have had acute tonsillitis at the time she developed septicaemia. I saw her two months later, and she was in a pitiful condition of extreme marasmus and pains in all the joints with slight pyrexia and pulse over 140. She had had various abscesses before I saw her and was removed from hospital as the parents preferred her to die at home. She

eventually recovered completely except for the right hip joint, which fifteen months later shows marked changes on x-ray examination although it is quite painless and freely movable.

Another disappointment was in a boy aged 17 who had two peritonitis abscesses in four months. I prepared him with gargles and paints for a month and then removed the tonsils satisfactorily as I thought. Put a month later he developed another abscess and the empty tonsillar fossa could be seen behind it. That was four years ago and he has grown considerably and has not been troubled with his throat since.

A child aged 6 had his tonsils and adenoids removed elsewhere for frequent colds. There is not a scrap of tonsil to be seen although he is a mouth breather. Since the operation he has had cold summer and winter alike almost continuously. He is said to have thickening in one maxillary antrum.

Is it possible to know beforehand whether a child with enlarged tonsils will be benefited by operation, or whether it would be better simply to administer thyroid or some other remedy. I am convinced that the operation cannot be judged solely on the appearance of the tonsils after removal or of the throat from which they came.

I should like to see carefully compiled figures from a school medical officer, spread over a number of years mentioning indications for tonsillectomy whether there were general symptoms or whether the tonsils were removed simply on account of their bulk, weight curve before and after operation opinion of the teachers and parents on the effect of the operation.

After confession of so many failures perhaps I may be excused for signing myself

August 8th

NEWELL

### ACUTE RHEUMATISM IN CHILDREN

SIR,—Your interesting review of the report by the Ministry of Health on Acute rheumatism in children its relation to heart disease in the JOURNAL of July 30th (pp 187-188) suggests one or two points perhaps worth more than a passing thought.

We read in the second paragraph "The prevention of its (rheumatism's) disastrous cardiac sequelae is a question of ways and means. The children must be received into suitable institutions. Poor homes, not the poor, but of children attending the public elementary schools" need reforming. Such reform involves questions of general culture, education, the standard of living, and kindred subjects, and its consideration would afford useful employment for our politicians.

With regard to suitable institutions, and all which that involves it is by no means so unquestioned that the results of the national treatment of tuberculous are commensurate with the expenditure that we should be ready to launch out into similar institutional expenditure for another disease which our present knowledge suggests, invades certain types of homes and avoids other types?

Who should carry out the investigation of the questions suggested, and others, in the homes of the school children. Possibly at once the thought comes that the medical inspector of school children (school doctor) with the school nurse and health visitor, are the very persons to do this work. Do their several occupations their knowledge of these homes and their breadth of outlook on social matters generally, make them most suited for such an investigation?

Who visits these homes so frequently, who knows so much about the standard of living who would be so interested that the children of his patients should be sound and healthy as the general practitioner attending one or both parents and probably the children also—as members of a juvenile club.

Government and public health medical officers, accustomed as they are to devising efficient schemes for any useful purpose could surely present some plan to interest the general practitioner and to try his knowledge and experience on this matter for the public good. It would need to be a plan which aroused his interest did not involve much clerical work and was recompensed by a suitable fee.

Further, the association of some general practitioners working under the National Health Insurance Acts with the official medical officers would result in a more useful scheme than if they were left out. In addition, it would be a practical example of the value of the private practitioner in matters of public health—I am, etc.,

## THE LUNACY LAW AND MENTAL DISORDERS COMMITTEE

SIR,—In your leading article of August 6th (p 221) you surmise that the non-acceptance of this committee's Memorandum by the recent Representative Meeting seems "to have been due in the main to a feeling that members had not had sufficient time" to consider the document. What motive determined the attitude of the silent members of the meeting no one, of course, can pretend to know, but those who criticized the Memorandum in speech produced reasons for their opposition other than the one which you present. That a Memorandum on so important a topic was submitted in so hurried a fashion might well excite comment, but the opposition also found place for serious criticism within the four corners of the document itself.—I am, etc.,

London, W 1 Aug 20th

C O HAWTHORNE

## THERAPEUTIC ABORTION

SIR,—In view of biochemical investigations and clinical observations published during recent years it is surprising to find that Dr H S Davidson (as reported in the BRITISH MEDICAL JOURNAL of August 20th, p 308) still advocates the practice of therapeutic abortion in certain cases of hyperemesis gravidarum.

Surely it has been conclusively demonstrated that the ill effects of pregnancy vomiting are essentially due to starvation (carbohydrate depletion) and, in the more severe degrees, to dehydration. These two factors adequately account not only for the usual ketosis and associated biochemical deviations from the normal, but also for the prurience, oliguria, and albuminuria which may characterize cases that have been allowed to pass from bad to worse. Obviously we must further take into consideration the effects of physical strain and increased abdominal pressure, but it is entirely unnecessary to assume the influence of a mysterious "pregnancy toxin," and for that reason to destroy and remove the embryo.

The aims of treatment are perfectly definite, and merely involve the introduction of carbohydrates and fluids into the patient's system by one means or another. Admittedly this is not always easy, but in the vast majority of cases these objects are attainable by simple measures of suggestion and persuasion, and even artificial feeding is very rarely indicated.

To terminate the pregnancy represents a complete confession of failure.—I am, etc.,

London W 1 Aug 21st

FRANK COOK

## CLINICAL VARIATIONS IN DISEASE FROM THE HISTORICAL POINT OF VIEW

SIR,—Sir Humphry Rolleston, in his magisterial address on this subject, when discussing the question of encephalitis lethargica (BRITISH MEDICAL JOURNAL, August 6th, p 208) mentions Tricot-Royer's interesting discovery of a contemporary poem relating an epidemic of hiccup in Flanders in 1413.

The importance of this lies in the fact that epidemiologists have always admitted the prevalence of "influenza" of the "knock-out" type in France and Italy in January and February, 1414. Those who see in epidemic hiccup a *forme fruste* of encephalitis lethargica must then at least agree that the geographical and temporal relation between epidemics of hiccup and of influenza recently noted did so obtain in 1414—five hundred years ago.

The point is further stressed when we realize that the epidemic of influenza mentioned by Hirsch as having occurred in 1411 was none other than the epidemic that did occur in 1414. As I have shown in *Influenza: Essays by Several Authors* (p 71), Pasquier—the sole authority given by Hirsch for the 1411 affair—was evidently misled by the error of someone who transcribed part of the account given of the 1414 epidemic in the *Journal d'un Bourgeois de Paris*.—I am, etc.,

London W 1 Aug 21st

F G CROOKSHANK

## RESISTANCE TO TUBERCULOSIS

SIR,—In your summarized report (April 2nd p 624) of a paper of mine on "Tuberculous lesions found in 800 Australian necropsies," read at the Australasian Medical Congress in Dunedin, New Zealand, in February, an error has crept in, owing to the line "No tuberculous foci detected" being mistaken for the words "Number of (No of) tuberculous foci detected." The correct figures are as follows. In 800 records the results were: No tuberculous foci detected, 527 (66 per cent); slight lesions present, possibly tuberculous, 43; tuberculous lesions present, 230 (28.7 per cent).

The account is printed reads: Number of tuberculous foci detected 527, instead of no tuberculous foci detected. If this remains uncorrected it may give a very erroneous idea of the prevalence of tuberculous lesions in Australia.—I am, etc.,

## BRITISH DOCTORS IN MADRID

SIR,—I practised in Portugal from 1920 to 1922, and during that time had only cordial relations with my Portuguese confreres. I therefore feel that it is for me to correct the biased evidence which has apparently been given before the General Medical Council by someone, acting on behalf of the British Embassy, who is either hopelessly incompetent to give this information or has made intentionally incorrect statements.

On looking up the regulations in the Year Book of the Faculty of Medicine of Oporto, published in 1920, I see that the fees payable on taking the examination for the degree of Doctor of Medicine amount to 300 escudos, not 3,000 as you state, equivalent to between £3 and £4, not £300 as you state. The escudo is at present worth 2½d.

Fees charged by English doctors are out of all proportion to those charged by Portuguese, and I can well understand the indignation of the latter, who have to work hard for a mere pittance, and who see English doctors practising in their midst among wealthy patients and making what to them appear to be fabulous incomes. These English doctors are of course, looked upon as unqualified, and cannot give death certificates. Until I took my degree in 1922 in Oporto I, too, was unable to give death certificates, and had to get a Portuguese doctor to cover me.

If the General Medical Council wishes to legalize the position of English doctors in Madrid, the equitable way would be for the Council to seek reciprocity with the Portuguese Government in the matter of registering medical qualifications.—I am, etc.,

ST GEORGE B DEFEIS GRAY,  
M D Oporto, M B, B S Lond

Mové Aug 22nd

\*\* Dr Dehisc Gray will find the full text of the correspondence between the Privy Council and the General Medical Council in the minutes of the Executive Committee of the latter body of July 25th, 1927. The fee for the degree of Doctor is there given as escudos 3,000, but the error of stating this to be equivalent to £300 was ours.

## Obituary

HARVEY LITTLEJOHN, M.B., C.M., B.Sc. (Ed.),  
F.P.C.S. (Lond.)

Professor of Forensic Medicine in the University of Edinburgh. We announced last week with deep regret which will be shared by all his old students as well as by everyone who had the privilege of his acquaintance the death of Professor Harvey Littlejohn. He had occupied the chair of forensic medicine in the University of Edinburgh since 1906.

We may well begin our short account of his life by quoting what has been written for us by the President of the Royal College of Physicians of Edinburgh for several years better than he or had ampler opportunities

of appreciating his great qualities. Those who did not know him personally will find at a glance in the characteristic portrait here reproduced physical evidence of what Professor Robert Carswell with regard to Littlejohn's high and energetic personality and his acute and penetrating intellect.

The death of Professor Harvey Littlejohn creates a greater social gap in medical and academic circles in Edinburgh than would be caused by the loss of any other medical man for his energetic, witty and attractive personality made its presence felt in every company. His figure was slim, agile and graceful, his intellect was alert and piercing, his disposition was human, sociable, and humorous, and with these qualities he combined soundness of judgement, feeling of responsibility, and a sense of justice. It is not surprising that he was asked to fill many important posts for he was without doubt one of the greatest personalities in Edinburgh and one of its best and most useful citizens.

He possessed the gift of eloquence, and was unsurpassed as a lecturer. Fortune seems to have lavished every qualification on him with a generous hand for this purpose. He possessed the knowledge and had acquired the experience which is a *quæ non*, he had the faculty of presenting the dry facts of his subject in an attractive form. He was a born raconteur with dramatic talents of the highest order. He could illustrate his points liberally with apt and interesting reminiscences which held the attention of his audience and, needless to say, the principles which he desired to drive home were never forgotten by his class and the process of instruction was a pure joy. He shone at his brightest at the meetings of the Faculty of Medicine, and he was the greatest dean we have had in our lifetime. His breadth of view, his grasp of affairs, his clearness of exposition, his accuracy of judgement, and his lightning-like intuition were remarkable. No other member, no other half a dozen member, carried the same weight. The note he made of his wit at one time to overcome irascible opposition, at another to smooth and obliterate ruffled feelings, was a delight to watch in operation.

"He took the deepest personal interest in the welfare of the medical students. When he discovered that anyone had been neglecting his work, the culprit had to appear before the dean and explain the reason why. This was an innovation and not popular with all, but Professor Littlejohn's high sense of duty would allow nothing to stand in its way. In the end he came to it that all incorrigible 'chronics' (amusing characters, many of them) were removed. He has not received full credit for this useful reform for the class of student was a slur on the university and a source of contamination."

"Like his father before him, Professor Littlejohn was acknowledged to be one of our greatest experts in medical jurisprudence. He gave his evidence simply, clearly, and directly, and it was always impressive. With

his forensic gift he was a most dangerous man to cross-examine, if he chose to do so. He has ever enjoyed a reputation in Parliament House (the Scottish Courts) which is one of the greatest tributes to his character of being moderate, just, and fair in his evidence on any examination."

Professor Littlejohn was police surgeon and adviser to the Crown on all criminal matters. The secrets that were revealed in his room may be imagined and many of the problems on which his advice was asked must have been of a very serious nature, affecting reputation and life. It is certain that no more humane, more just or wiser counsellor could have been found. His father, Sir Henry Littlejohn, a medical officer of health for Edinburgh, made a reputation before him, of which he was very proud, but he has added to the laurels of the family.

This is a true picture and may help to explain the admiration with which he was regarded and the affection in which he was held.

Henry Harvey Littlejohn was born in 1862 and educated at the Edinburgh Academy and the University of Edinburgh. After taking the degree of M.A. he commenced the study of medicine and graduated M.B., Ch.B. at Edinburgh in 1886. With the intention of following the practice of which his father the late Sir Henry

Littlejohn was a distinguished representative he immediately proceeded to study public health, and graduated B.Sc. in that department in 1888. At this period also, shortly after graduation, he spent some time as resident physician at the Marston Hospital under the late Sir Halliday Croom. After a period of study at the medical schools of Vienna, Berlin, and Paris he took the L.P.C.S. in 1889 and proceeded in the following year to the Fellowship of the Royal College of Surgeons of Edinburgh. He had been a Senior President of the Royal Medical Society, in which he took a lifelong interest. At a later date he became a Fellow of the Royal Society of Edinburgh.

For some years after graduating in public health he acted as assistant to his father, Sir Henry Littlejohn, in the latter's class of medical jurisprudence, and at the same time helped him in the duties of the medical officer

*John B. Cunningham*  
*Henry Harvey Littlejohn*

of health for the city of Edinburgh. In 1891 he was himself appointed medical officer of health to the city of Sheffield, a post he held until 1897, when he returned to Edinburgh and commenced to lecture in medical jurisprudence at Surgeons' Hall, and at the Edinburgh School of Medicine for Women. He continued to act in these capacities until 1906, when he succeeded his father in the chair of medical jurisprudence in the University. At this time the University chair, which had hitherto embraced the two subjects of medical jurisprudence and public health, was divided by the appointment of a professor of public health. As a lecturer Littlejohn had a great gift for presenting the facts of his subject in a concise, lucid, and at the same time attractive form. The important points in his lectures were made to stand out by the striking manner in which he presented them, and by a great wealth of interesting reminiscence with which he was able to illustrate them; his lectures were not only interesting and amusing at the time of their delivery, but remained a permanent memory with his students.

In 1906, also, Harvey Littlejohn was appointed chief police surgeon in Edinburgh, and thus brought him into association with the Crown authorities, so that he virtually succeeded Sir Henry Littlejohn as a frequent witness for the Crown in criminal cases in the High Court. Sir Henry Littlejohn had gained a great reputation as a medico-legal witness, and this was speedily equalled by his son. He was generally recognized as an expert witness who gave his evidence with great lucidity and conciseness, and at the same time was distinguished by his reasonableness and fairness under cross-examination.

Harvey Littlejohn was a clear, concise, and incisive a writer as a speaker, but he could not often be induced to contribute to current medical literature. He wrote an article on post-mortem examinations for medico-legal purposes in the *Quarterly Journal of Medicine*, 1902, and another on post-mortem appearances in the drowned in the *Edinburgh Medical Journal* in 1903. He contributed an article on medical jurisprudence to the *Encyclopaedia Medica*, and about two years ago published a book on *Forensic Medicine*, remarkable for the number of instructive illustrations it contained. He thus carried out the principle by which his teaching was always guided—that the subject must be taught objectively. In concluding our review we said of the volume that it was worthy of the distinguished author and the great school to which he belonged. He had inherited from his father a fine museum of forensic medicine, and had himself added to it many most interesting specimens; the collection is probably the most complete in Great Britain, and one of the finest in Europe.

Many addresses were delivered by him to the various societies of which he was a member, these included the Epidemiological Society, the Medico-Legal Society, the Society of Medical Officers of Health, and the Society for the Study of Inebriety. At the last International Medical Congress held in 1913 he was President of the Section of Forensic Medicine.

He was for many years a member of the British Medical Association and its very good friend, as also of its *Journal*. Though friendly, he was a candid critic, and a conversation with him about the conduct of the *Journal* was a tonic. He was secretary of the Section of Public Health when the Association met in Montreal in 1897, president of the Section of Public Health and Forensic Medicine in Sheffield in 1918, and for some years treasurer of the Edinburgh Branch, he had been elected president of the Section of Forensic Medicine at the Annual Meeting in Edinburgh this year, but owing to rapidly failing health was unable to take his place.

During part of the twenty-one years through which he held the chair of forensic medicine at Edinburgh University, Professor Littlejohn acted as dean of the Medical Faculty. He interpreted the duties of this post as carrying with them great responsibility in regard to the welfare of students, and, as Professor Robertson has said above, he did not shrink the duty of administering a fatherly admonition to students slack in their work and, if necessary, did not hesitate to remove from the University a number of "chronics" who exercised an unsatisfactory influence upon their younger fellow students. Professor Littlejohn was for

several years a member of the Board of Managers of the Royal Infirmary. He was for a time Commandant of the Medical Unit of the Officers' Training Corps in the University, holding the rank of Major R.A.M.C.(T). When, in 1915, the University of Edinburgh appointed him to be its representative on the General Medical Council, he quickly made his mark. He did not speak very often, but when he did what he had to say was to the point, and his influence with the Council was therefore very considerable. He was much interested in its work, and had served as a member of its Public Health Committee since 1916, and of its Education Committee since 1920. He was a diligent attendant, and always managed to fit in with the meetings of the Council the winter holiday he was in the habit of taking in the hope of mitigating the bronchitis and asthma to which he was a martyr.

Professor Littlejohn was very sociable and witty, and the vision of his alert and graceful figure in an Edinburgh street was always the prelude to an amusing and cheerful meeting with any friend he happened to encounter. His death will be a great loss both to the city and University of Edinburgh, as well as to the many organizations in which he took an active interest.

He was unmarried. The interment, subsequent to cremation, took place on August 19th, at the Dean Cemetery, and was attended by a large number of professional colleagues, including representatives from the town council, the University, the Royal College of Surgeons, and the Board of Management of the Royal Infirmary.

Dr J. S. C. Haslam (Assistant Director, Bureau of Hygiene and Tropical Diseases, London) sends the following tribute:

Others are more able and more fitted than myself to pay tribute to Professor Littlejohn's renown as a medical jurist. First numbers of Edinburgh graduates will never forget his lecturing, with its dramatic power, originality of gesture and characteristic mannerisms. Perhaps, too, many will remember him as dean of the Faculty of Medicine, dispensing counsel and correction to such as had deviated from the paths of academic rectitude. It was characteristic of Littlejohn that he had his real kindness behind a certain brusqueness of manner. As University assistant and as friend I had the privilege of getting behind what most students called his "pepperness," and of knowing a side of the man little known to the great numbers who passed through his class. One August Bank Holiday three ragged children carrying a bottle of milk and a few bins were walking a little wearily, for it was hot—along George IV Bridge. Professor Littlejohn stopped them, asked where they were going, and on being told "To Granton for a picnic," provided the tram fares for the party and a sixpence for further refreshments. The staff of the Edinburgh Children's Shelter could tell of many kindnesses to the little waif residents—of surreptitious pennies, and of tricks by Sam, the cocker spaniel. These are small things perhaps, but they illustrate the human side of Littlejohn which made him the friend and chief he was, a side which he seemed almost at pains to conceal, but which to those who knew it, seemed the mainspring of his personality.

[The photograph reproduced is by Mr. A. Swan Watson, F.R.P.S., Edinburgh.]

Dr T. P. Greenwood, who died suddenly on August 15th, while getting into his motor car in response to an urgent call, was born in November, 1853, and received his medical education at University College Hospital. He obtained the diplomas M.R.C.S. Eng. in 1875 and L.R.C.P. Ed. and L.M. in 1878. After holding the appointments of junior house-surgeon to the Derbyshire General Infirmary and house-surgeon to Stamford Infirmary, he became assistant, and later partner, to the late Dr. Roth in Stamford, and eventually succeeded him. He was senior surgeon to the Stamford Infirmary, surgeon to Browne's Hospital and Tuesdale Hospital, Stamford, and medical officer of health to the Stamford Rural District, in which capacity he put in excellent work, especially in regard to housing the provision of scavenging, and the building of a small pest hospital. He was largely responsible for the erection and equipment of a maternity and children's ward at the Stamford Infirmary. He gave active support to the British Medical Association, and was vice-president of the Midland Branch in 1899, and president in 1903 and 1925. He was vice-chairman of the Kesteven Division in 1915 and 1923, and chairman in 1922; he was also an associate member of the Lincoln Division. He is survived by his widow and

three daughters. A colleague writes: Dr Greenwood was one of the few survivors of the old type of general practitioner. His chief aim in life was his professional work, and he succeeded in building up a very large general practice in and around Stamford. His colleagues had a very high opinion of his skill, and he was often called in consultation with his professional brethren for miles around Stamford. His principal amusement was fishing and he scarcely ever missed seeing the Ipeom classie in fact it was his one holiday in the year. He belonged to the Badminton Club. In politics he was a strong Conservative, and a vice-president of the Stamford and Rutland Conservative Association. His death has caused a great gap in the medical world of South Lincolnshire and Rutland which it will not be easy to fill.

Dr HORACE CLEWTON NIXON, who died on July 15th, at the age of 50 was born in Staffordshire, and received his medical education at Edinburgh, Dublin, and St Bartholomew's Hospital. He graduated M.B., Ch.B. in 1900, and proceeded M.D. four years later. After holding the post of hon. physician at the North Staffordshire Infirmary and Eye Hospital, and senior house-surgeon at Huddersfield Infirmary he practised for some years in Harrogate. During the war he held a commission as temporary surgeon in the Royal Navy and was later medical officer in charge of outpatients at Farnham Military Hospital. After the war he became medical superintendent of the Ministry of Pensions Hospital at Harrogate when it was closed he commenced practice in Bath and held the appointments of physician to the Royal Mineral Water Hospital and medical officer in charge of the physiotherapy department of the Royal United Hospital. He was a member of the British Medical Association, of the Bath Clinical Society, of the Bristol Medical-Chirurgical Society, and of the Three Arts Club at Harrogate. He composed many songs and performed music which were published under the name of Horace Clewton.

Dr EDWARD COLBY SHARPIN, who died at his residence in Bedford on August 4th was the eldest son of the late Mr Henry Wilson Sharpin, F.R.C.S. and was born in Bedford in 1859. He received his medical education at St Bartholomew's Hospital, he obtained the diploma of M.P.C.S. Eng. in 1882, and in the following year the L.P.C.P. Ed. and I.M. After holding the post of hon. surgeon at the Lincoln County Hospital he joined his cousin in practice in Bedford, and was appointed surgeon and later consulting surgeon to the Bedford County Hospital, consulting surgeon to the Bedford Central Provident Dispensary and senior physician and referee to the Royal Home for Incurables at Ixington. He was a member of the British Medical Association and served on the South Midland Branch Council 1886-7. Apart from his practice Dr Sharpin took great interest in gardening, he exhibited successfully in many parts of England and won the Royal Botanic Society's silver medal for carnations and pinks. He was also a keen sportsman and a good shot. For some years he was a member of the Bedford Town Council.

The following well known foreign medical men have recently died: Dr HENRI KOHLER of New York aged 68, attending paediatricist to Mount Sinai Hospital who discovered the buccal spots of measles, to which his name is attached, Dr ARTHUR ZIEGLER, professor of clinical paediatrics at the New York Polyclinic who played a prominent part in immunization of children against diphtheria and scarlet fever, died from accidental asphyxiation in a laboratory at the age of 45. Professor M. GROSSMAN, a Viennese otologist, aged 78. Professor C. ERICH FRITSCH of Berlin, who collaborated with Hitzig in the experimental physiology of the brain, aged 69. Professor P. KERN, a Budapest gynaecologist, of ropexy during an operation, aged 57. Professor WERMEL, director of the physiatric institute at Moscow, Dr V. V. VITKOV, professor of clinical surgery at the Nancy Faculty of Medicine, Dr ROBERT

PIQUET, professor of anatomy at the Bourdon faculty of medicine and a pioneer in the surgery of aviation, aged 50, in an airplane accident. Dr OTTONE BARNICCI, professor of morbid anatomy and director of the medical faculty at Sassari, aged 66, and Dr FRANCESCO DE PAOLI, professor of Surgery at Perugia.

## Medical News.

THE third revised report of the recommendations of the X-Ray and Radium Protection Committee has been issued by the National Physical Laboratory. Some slight alterations in detail have been made but in the main the requirements for efficient protection remain unaltered. Although some may think the conditions onerous, and the protection overdone it is at any rate wise to err on the side of safety, especially in view of the large number of x-ray and radium deaths and injuries. The danger of ultra violet therapy and the precautions to be observed are also dealt with. No hospital authorities medical or lay can afford to overlook the advice contained in the report, and this applies not only to buildings and apparatus but also to the suggestions as regards the working staff. Copies can be obtained on application to the Secretary British Institute of Radiology, 32 Vellie Street London, W.1.

A connection with the meeting in December at Cairo, of the congress entitled the *Journées Médicales d'Égypte* of which a preliminary notice appeared in our issue of April 30th (p. 820), it is now stated that promises of support have been received from the University of Egypt and the Society of Egyptian Medicine. The arrangements it was found, had gone too far to make it convenient to combine this congress with another proposed to be held late in 1928 in commemoration of the centenary of the death of *Ami* Hospital in Cairo.

A sum of £30,000 is required to repair the damage to the hospital of the Order of St John at Jerusalem and to bring the accommodation and equipment up to present requirements. It may be recalled that reference to the destruction of this hospital appeared in our issue of April 23rd, 1927 (p. 771).

THE Fellowship of Medicine announces that a fortnight's course will start on September 12th at the Queen's Hospital for Children including lectures operations and demonstrations and on the same date a three weeks course will begin at the Royal Westminster Ophthalmic Hospital. For a fortnight from September 19th the Royal National Orthopaedic Hospital will hold a special all day course with lecture demonstrations in the mornings and operations and out patient work in the afternoons. During the same period there will be another all day course in medicine surgery and the specialties at the Westminster Hospital. During October courses will be given in internal treatment at the Royal Free Hospital, cardiology at the National Hospital for Diseases of the Heart, diseases of children at the Victoria Hospital and Paddington Green Hospital, diseases of the throat, nose and ear at the Central London Throat, Nose, and Ear Hospital, electrotherapy at the Royal Free Hospital, gynaecology at the Chelsea Hospital, ophthalmology at the Royal Eye Hospital, tropical medicine at the London School of Hygiene and Tropical Medicine and neurology at the National Hospital, Queen Square. The Fellowship of Medicine has also arranged a series of lectures on practical hints on medicine surgery and the allied specialties. The first of the series will be delivered on October 17th by Sir Humphry Rolleston who will be followed on succeeding Mondays until Christmas by other physicians and surgeons. There will also be a series of weekly clinical demonstrations in medicine in surgery, and in ophthalmology given at various hospitals, free to medical practitioners. Copies of the syllabuses for all these courses may be obtained from the Secretary of the Fellowship 1 Wimpole Street W.1.

A. E. DEAN and CO. Holborn London have issued a new catalogue of apparatus required for deep seated radiation by means of x-rays. Special attention is drawn to the Isometric Group two sets of which have been supplied to the General Infirmary Leeds and have stood the test of time. The catalogue is well illustrated and the letterpress gives good descriptions of the main and accessory apparatus. The part dealing with the different methods of measuring dosage should be useful.

THE German Paediatric Society will hold its thirty eighth annual meeting at Badgastein from September 11th to 15th under the presidency of Professor Schloßmann of Düsseldorf.

Dr EMIL DE GRÖSZ of Budapest has published a sym pathetic address on Lister and Semmelweis in the Hungarian journal *Orvostudományok* for June 25th illustrated with portraits and accompanied by an abstract in English.

## Letters, Notes, and Answers.

All communications in regard to editorial business should be addressed to **The EDITOR, British Medical Journal, British Medical Association House, Tavistock Square, W C 1**

**ORIGINAL ARTICLES** and **LETTERS** forwarded for publication are understood to be offered to the **British Medical Journal** alone unless the contrary be stated. Correspondents who wish notice to be taken of their communications should authenticate them with their names not necessarily for publication.

Authors desiring **REPRINTS** of their articles published in the **British Medical Journal** must communicate with the **Financial Secretary and Business Manager, British Medical Association House, Tavistock Square, W C 1** on receipt of proofs.

All communications with reference to **ADVERTISEMENTS**, as well as orders for copies of the **JOURNAL** should be addressed to the **Financial Secretary and Business Manager**.

The **TELEPHONE NUMBERS** of the **British Medical Association** and the **British Medical Journal** are **MUSUM 9561 9562 9563**, and **9564** (internal exchange four lines).

The **TELEGRAPHIC ADDRESSES** are

**EDITOR** of the **British Medical Journal**, *Anthology Westcent, London*

**FINANCIAL SECRETARY AND BUSINESS MANAGER**

(Advertisements, etc.), *Articulate Westcent London*

**MEDICAL SECRETARY** *Medivocia Westcent London*

The address of the **Irish Office** of the **British Medical Association** is 16 South Frederick Street, Dublin (telegrams *Bacillus Dublin* telephone 4737 Dublin), and of the **Scottish Office**, 6 Drumsheugh Gardens Edinburgh (telegrams *Associate Edinburgh* telephone 4361 Central).

### QUERIES AND ANSWERS

#### SMUGA

"S" wishes to know whether, after complete circumcision in infancy, the secretion of smegma is diminished or suppressed.

#### HYPERIDROSIS

"THORICUS" who writes from the West Coast of Africa, asks for advice in the treatment of hyperidrosis of the palms and soles in a man aged 35. He has suffered from boyhood but the condition has grown worse during the last few years. While in the tropics, where he has spent most of the last five years, the condition disappears but reappears as soon as he reaches a cold climate. Stout leather shoes are saturated in an hour and the wearing of gloves is impossible, otherwise he enjoys good health. Various remedies, but not rays, have been tried without success.

#### TREATMENT OF GONORRHOEA

**Dr P C P INGRAM** (Newport Mon) writes **Dr R Cock**, in your issue of August 13th (p 267), asks for opinions as to the treatment of gonorrhoea by injections of hydrogen peroxide. It does not appear to be much in vogue. The only reference I can find is in **LAVIS** *Gonorrhoea* (Doesters' translation, second edition, London 1917), where it is mentioned last in a list of seventeen drugs that can be used. **Harrison** does not mention it in his book (Oxford Medical Publications, London 1919), nor in his article on the routine treatment of gonorrhoea (*British Journal of Venereal Diseases* vol 2 p 30) nor does **Hoffmann** (*ibid* p 233) or **Indassolin** (*ibid*, vol 3 p 160) in accounts of their methods. I think he will find that the most generally accepted opinion is that irrigation with potassium permanganate by Janet's method is superior to any form of injection, and its continued use in almost all the venereal disease clinics in this country appears to show that it is standing the test of time. While it is agreed that the best method of cure is to 'get the gonococci' early, more harm than good may be done by 'treating them roughly,' as the delicate mucous membrane of the urethra may have to share in that method with unsatisfactory results. Regarding the case he quotes were any of the recognized tests for cure tried after the discharge had ceased?

#### INCOME TAX

##### Subscriptions and Rent Proportion

"M M" inquires as to the admissibility of payments made in the form of subscription and asks whether the circumstances stated do not justify the deduction of more than half the rent, rates, etc. paid in respect of the premises used for private and professional purposes.

"\* \* \* Most of the refused 'subscriptions' are really payments for professional literature reasonably necessary for the work carried on, and the claim should be put forward on that basis. With regard to the premises the amount of accommodation used professionally—including that occupied by the professional staff—is abnormal, and *prima facie* two thirds would be reasonable. It is sometimes helpful to compare the personal accommodation with the balance of the rent etc., cost to see what is reasonable from that point of view. There is no statutory maximum or

minimum. 'M M' has a right of appeal to the District Commissioners or to the Special Commissioners, both bodies being of course, quite independent of the revenue department in such matters.

#### Motor Car Allowances

"L B S" elected to take wear and tear—that is, depreciation—allowance in respect of his car for 1926-27. The inspector of taxes has refused on that ground to grant any 'replacement' or 'obsolescence' allowance in respect of that car. The amount of the claim is £110 loss (£65+£45)—that is, £26.

"\* \* \* We suggest that 'L B S' should refer the inspector to Rule 7 applying to Cases I and II, Schedule D, Income Tax Act, 1918, which, as amended by the Finance Act, 1925, provides that "in estimating the profits there shall be allowed to be deducted so much of any amount expended in that year in replacing any plant or machinery which has become obsolete as is equivalent to the cost of the plant or machinery replaced after deducting from that cost the total amount of any allowances made on account of the wear and tear of that plant and machinery and any sum realized by the sale of that machinery or plant." The authority of the Caledonian Railway case is against the simultaneous allowance of "cost of renewals" and depreciation, but does not affect the right to the obsolescence allowance, which appears clearly to be due to our correspondent under the above quoted section.

#### Replacement of Car

"INQUIRER" bought a 16-h.p. car in 1913 for £200, he has been allowed £77 for depreciation and will sell the car this year for £15. He has bought (also this year) a secondhand 18-h.p. car for £75. What allowance should he claim?

"\* \* \* If 'Inquirer' will refer to the reply to 'L B S' printed above he will see the limitations under which an obsolescence claim can be made. In his case the result of deducting the depreciation allowances from the cost of replacing the old car is to reduce it to nil, and he can therefore claim nothing under that section. He might ask the inspector of taxes to continue to allow depreciation on the written down value of the old car, less the £15 received—that is on the £108, we understand that this is sometimes done in cases of hardship.

### LETTERS, NOTES, ETC.

#### CLINICAL VARIATIONS IN DISLASI FROM THE HISTORICAL POINT OF VIEW

**DR T. GEFALD GARRI** (Montecatini Italy) writes **Sir Humphry Rolleston's** instinctive paper (*JOURNAL*, August 6th, p 203) should be carefully read and digested. I doubt very much, however, if much accurate information can be obtained concerning disease by the pathological study of *Egyptian mummies*. This was shown recently in the case of *Tutankh Amen*. Nothing remains of the original but 'skin and bones' well pickled, the same applies to the viscera which undergoes various processes. About the existence of certain diseases—such, for instance as aneurysm—there can be no doubt, but the existence of such conditions as, for example, arterio-sclerosis and rheumatoid arthritis (always a rare entity in *Egypt*) is questionable. From a study of the symptoms described in the papyri—a fairly reliable method although there appears to be no unanimity concerning even the name of the heart—over two hundred different diseases can be differentiated and, generally speaking, the incidence of such morbid conditions has not materially changed among the present inhabitants of *Egypt*. As in ancient times, diseases of the eye, skin, intestines, bladder and urinary tract figure prominently. It is a pity that there should be so much exaggeration concerning the "wonderful knowledge" of medicine possessed by the Egyptians. Authorities like **Maspero** and **Reisner** it was not worth considering. The basis was not disturbed by normal function, but was not disturbed by any in violence, which could only be met by ordering a prescription for "expelling or terrifying such a disease," caused by them.

#### CAUTION

ON April 3rd 1926 (p 640), members receiving begging letters from a Mrs E M Etheridge were advised that before giving assistance they should communicate with the Secretary of the Charity Organization Society, Denison House, 296, Vauxhall Bridge Road, S W 1. From information recently received it appears that Mrs Etheridge is continuing her appeals, but from an address different from that used last year.

#### VACANCIES

**NOTIFICATIONS** of offices vacant in universities, medical colleges, and of vacant resident and other appointments at hospitals, will be found at pages 32, 33, 34, 35, and 36 of our advertisement columns and advertisements as to partnerships, assistantships, and locumtenencies at pages 35 and 37. A short summary of vacant posts notified in the advertisement columns appears in the *Supplement* at page 124.

THE  
**British Medical Journal.**

THE JOURNAL OF THE BRITISH MEDICAL ASSOCIATION

LONDON SATURDAY SEPTEMBER 3RD, 1927

**EDUCATIONAL NUMBER SESSION 1927-28**

**An Address.**

OF

**AMERICAN METHODS IN MEDICAL EDUCATION**

DELIVERED TO THE CONGRESS OF THE AMERICAN COLLEGE OF SURGEONS  
IN THE HOTEL DIEU, MONTREAL, OCTOBER, 29TH, 1926,

BY

SIR ANDREW MACPHAIL, KT OBE BA MD, CM, LL D, MRCS, FPSC  
PROFESSOR OF THE HISTORY OF MEDICINE MCGILL UNIVERSITY

MONSIEUR LE PRESIDENT ET MADAME LA REVERENDE MERE SUPERIEURE Dans cet Hotel Dieu cet hospital de Dieu, le foyer de la medecine au Canada, il y a trois siecles, sanctifie par la devotion de vos sœurs et par la memoire de Jeanne Mance, il peut se faire que l'esprit de ce milieu descende sur nous. Sous l'influence de cet esprit nous pourrions decouvrir que la nature n'est qu'une expression de la volonte divine que l'etre ideal suit l'ordre de la nature et vit en accord avec cette volonte que la nature a faite—corps et ame. Tout ce moderne titonnement s'utilise pour trouver l'effet de l'ame malade sur le corps malade n'est que l'effort pour decouvrir le secret que vous n'avez jamais perdu, le pouvoir de la religion. C'est un effort pour répondre à la question du Maître. Quid facimus est dicere. Dimittuntur tibi precolo tua in dicere Surge ambula. Peut-être au moins apprendrions-nous en ce milieu, l'humilité d'Ambroise Paré. Je l'ai parvenu Dieu le garant. Cela est la science définitive.

Gentlemen I was merely saying a few words to the Reverend Mother Superior, who has left her cloister to honour us with her presence.

The principles of surgery I learned from a pupil of Lister. Operative surgery I observed under the hand of that first of modern English surgeons, at the time when he was perfecting the operation for perityphlitis is the term by which in those days appendicitis was described. In the intervening years surgical principles have not changed. Surgical procedure has developed, and change is one of natural growth. But education in those principles and in the methods of practice in surgery and medicine have so changed that we are now in a new world.

To restrict my theme within the compass of an hour I have chosen to examine American methods alone. As I am speaking to the American College of Surgeons I shall further restrict my scheme mainly to surgery and as you honour me with your meeting in Montreal I shall consider those methods only in so far as they affect the development of our own education. To appraise the effect upon ourselves would be an impertinence. Your institutions are sacred to you and not to be touched by an alien hand. The fate of Uzza shall be my warning.

Those methods invade this country by four routes. The American Medical Association through the Council on Medical Education and Hospitals, inspects and classifies our medical schools, the inference drawn from that inspection has been published at irregular intervals. The Association of American Medical Colleges inspects all schools, retains its membership. Most schools have eagerly

sought, or accepted, an invitation to come within the circle. Few schools have had the hardihood to decline that jurisdiction, willing to wear the invidious distinction of standing alone. The Boards of many States will grant licenses only to graduates of schools specified by the American Medical Association. Finally, the American College of Surgeons inspects and grades our hospitals, and so the influence is complete. There yet remains, however, the less official operation of the Carnegie Foundation for the Advancement of Teaching, and the Rockefeller Foundation, but these are not of pressing importance to our theme. They have spent vast sums of money upon us, but no further expenditure seems to be imminent, and never at any time did they seek to exercise sequential control.

Proceeding still further with these self-denying restrictions I shall define the modern period as beginning in 1876 the year in which Johns Hopkins was founded and more especially with the year 1910 in which the Carnegie Foundation brought us face to face with the revival of medical education in the United States. Up to that time we had been left free to develop our own inherited methods in native obscurity. In these sixteen years our medical education has been profoundly altered and it is of this period I shall continue to speak.

In the year 1910, the beginning of this modern era, an exhaustive survey of medical education in the United States which had been undertaken five years earlier for the Carnegie Foundation by extremely competent observers, was complete. Their researches were extended into Canada and the results were published in Bulletin Number Four by Abraham Flexner with an introduction by Henry S. Pritchett the President.

The necessity for such a survey in the United States was apparent. The President declared that certain facts were revealed—namely that there was in that country an enormous overproduction of uneducated and ill-trained medical practitioners that there was a very large number of commercial schools sustained in many cases by advertising methods, through which a mass of unprepared youth was drawn into the study of medicine. With those conditions we in Canada were not especially concerned, but we are entitled to believe from a second report that they have been much altered for the better. We are even yet vitally concerned with the impressions formed upon the minds of those trained investigators by conditions in Canada.

According to their own account (p. 326) the high quality of instruction offered by McGill and Toronto "proves that

our trouble in the United States has been at bottom not less one of low ideals than of low standards. Indeed, "they add in general terms, 'where ideals are low' [in the United States] 'there is no standard, and where ideals are high' [as in Canada] 'the standard, even though low, is at any rate so definite that it furnishes a sure starting-point towards a clearly apprehended goal. The low-standard school in the United States has had no such starting-point and no such goal'."

With every desire to be polite, it is useless to pretend that the detailed appraisal of medical education in Canada met with universal acceptance. In so far as it assumed to describe conditions in the Maritime Provinces, the Medical Society of Nova Scotia declared formally that the Report was "prejudiced, inaccurate, and misleading." The answer is to be found in "the good standing and success of the practitioners who received their education" in the school that was condemned.

Without entering too closely into this controversy, it may be observed that when two sets of men, both equally disinterested and sincere, are in profound disagreement, they are thinking in different terms and dealing with different categories. To those American investigators a school meant buildings, equipment, and machinery, or "plant" as they themselves would say. To the medical profession of Nova Scotia a medical school derived its virtue from the quality of the human beings who taught and learned in the school.

This divergence of opinion is disclosed by the procedure of the examiners. They arrived in Halifax at about one o'clock of a Saturday morning by a train which in those days was punctually late. We are not informed what hotel they went to, but anyone who has had a similar experience in Halifax will readily understand that they must have been in a peevish mood. They were determined to leave by the only train shortly after noon. Otherwise they would be compelled to remain in Halifax over the Sabbath. In four hours they visited a university, a medical school, and two hospitals. Their research could not have been very profound, no officer of the school ever saw the delegates, or even knew of their arrival until after they were gone.

Then escape from Queen's University in Kingston was not so easy. Their complaint is that its location "on an inconvenient branch-line greatly aggravates the difficulties due to the smallness of the community." They dealt with externals. Their especial grievance against the London medical school was that the janitor carried the key of the library, but they did not specify by whom, in their opinion, the key should be carried.

The contrary view that virtue lies not in plant alone was fully enforced by Dr. John Stewart at the meeting of the Nova Scotia Medical Society, when the Bulletin was under discussion. He was at that time, and is happily yet, the professor of surgery in Dalhousie, in peace and was the perfect physician, "a pattern" in the old Hippocratic sense. He brought comfort to his colleagues by reminding them that "it is the man more than the laboratory that is essential, that there were no pathological laboratories when Lister developed antiseptic surgery, Koch, a country practitioner in a lonely Prussian village, had no laboratory but what he could construct for himself, Trudeau, alone in the Adirondacks, demonstrated the main facts in our knowledge of tuberculosis." This same John Stewart had learned his surgery from the very Lister himself. We need not wonder that he refused the stigma "mercenary."

How, then, shall we account for those ideals in Canada, which the Bulletin commends, and their absence at that time from the United States, which the Bulletin deplored? We did not create those ideals, we required them by inheritance. They were brought by the military surgeons, French and English, who implanted them in our hospitals and schools, primitive as those institutions were. There they were nourished. They yet exist and grow.

Those surgeons in turn inherited them from the schools of Edinburgh, Dublin, and London, and by a collateral inheritance from Leyden, Vienna, and Paris. Those who are cautious may trace the stream backward through the French and Italian Renaissance, to Montpellier, Padua, Bologna, and Salerno, even to Alexandria and finally to

the ultimate Kos and Knidos, where those ideals for all time were enunciated by Hippocrates himself.

In the United States, on the contrary, the thread of history was broken in 1776, when those communities cut themselves off from European civilization. For exactly a century the tradition of medicine was lost. It was revived in 1876 by the founders of Johns Hopkins, and was enriched by influences emanating from this country. By the year 1910 these old ideals had so increased in strength in the United States that their new possessors were eager to bring them back in a modified form to us, who had never lost the originals.

They came to us with the demand that we accept the methods equally with the ideals themselves—and most of them arrived by way of Toronto. This dogma might be stated in alternative terms. The conditions were set forth, we were left free to accept or refuse. But the choice was a hard one. Refusal meant the exclusion of our graduates from those rich fields. From that comparatively recent date, 1910, American methods have dominated medical education in Canada, but those methods changed so swiftly that we found ourselves in possession of many of them after they had been abandoned as impracticable by their originators. Many of these American discoveries in medical education are not discoveries at all. Some were discovered long ago, and abandoned as fallacies, others are yet in common use. The out-call service for senior medical students discovered in Nebraska has been a compulsory part of the medical curriculum in Edinburgh for nearly three years.

Again, the system of preliminary education in the two countries was different. In Canada there were few universities, but many colleges and grammar schools. In the United States there were many universities and few schools leading up to them. In those Canadian colleges, and even in some grammar schools, the teaching was quite as good and quite as comprehensive as in the first year of many universities, American or Canadian either. In the laudable effort to enforce some standard of entrance two years in a university were specified, and we were compelled to conform, else our graduates would be denied admission to practice in many of the States.

As a partial result the course in the Canadian medical schools fell into utter confusion, and many of the calendars still defy analysis or understanding. This confusion was due also to the impossible policy of making the medical faculty responsible for the preparation of students to enter the medical course. This policy has now been abandoned by all Canadian universities except one. I am bound to confess, however, that our obedience to these alien regulations is not so perfect as might appear from our calendars, but we had not far to go for a lesson in the evasion of those laws that do not meet with general approval.

In the best schools for forty years the course was four years in length, whilst in the American schools three years was the exception and two the rule. At McGill the course has never been less than four years for the last hundred years. In the effort to stretch out the course to conform with the new American standard, years called "pre-medical" and "post-medical" were added. The essential of these pre-medical years was that no medicine should be taught. For our students in those days, with their sound preliminary education already acquired in schools and colleges, these years were not so necessary.

For some time the two years in a college or Arts faculty was not absolute. The saving clause "or its equivalent" mitigated the rigour. That saving clause drops out, and a prospective student who wishes to graduate is faced with seven, or at least six years of college and university life. In Dalhousie a student entered the first year in Arts in 1924, last year he was a freshman in medicine, by these changing courses he is again a freshman for the third time. The boy has had no failures, and he does not play football, now he defies the faculty to find another first year for him, but his father gravely fears that technical academic ingenuity has not yet been exhausted. Even after seven years the student has not become a scientist, his aptitude for practice is dulled, his enthusiasm vanished. He has missed the training of a medical corporal, or a

boy scout and the priceless experience of a nurse. When he begins practice he is too old to learn those homely arts. He is shy of the gift of healing lest he might fall into the category of irregular practitioners. He thinks his duty done when he gives to the disease a name. According to returns from fifty two American schools 59 per cent of the graduates in 1915 were from 35 to 39 years of age, none were under 30. In 1920 the number between 30 and 34 years of age was 59 per cent, but the average age was even higher.

In the United States it has been found necessary to erect certain barriers and to segregate sections of the community according to colour race and religion. This practice is not new. In England Catholics and Presbyterians alike were at one time debarred from the universities, but all those restrictions were swept away nearly a hundred years ago. In Canada also the medical schools are free to all. As the American schools raise the bars the surplus falls upon us and it falls so suddenly that we find some of our classes largely filled with American students—not the average of American students but many who are deliberately excluded from their own schools.

For four years Dalhousie had not a single American student. In the next year more than half the students came from the United States, and if one can judge by their names they are precisely those who have been excluded from the American schools. Toronto is a Government institution and may quite properly restrict its students to the province by which it is supported. McGill is a private corporation and has no such obvious means of defence. In the medical faculty more than a third of our time and revenue is devoted to American students, who return to their own country as soon as they graduate.

On occasion students are exported wholesale into our schools. The General Medical College of Chicago was compelled to close six years ago. Through the good offices of the Council of the American Medical Association students were exported in bulk to Dalhousie where they were gladly received. They graduate this year and form one-half of the class.

This large number of applicants creates in us a false sense of prosperity. At McGill we limit a year to 100, whilst 500 apply, but the same applicants may apply to several schools as pass engers will put down their names for a berth with several railway companies and in the end choose the one they think the most convenient. More than half the American students accepted this year had applied to other schools. In the meantime under this influx the fees are raised to our own students also for the university treasurer is human. It now costs a student eight thousand dollars before he begins to practice. That eliminates nearly all but the rich, for the heroic self-supporting student yet remains it eliminates the son of the general practitioner it eliminates finally the general practitioner himself for a graduate who has spent that sum and seven years will not be content with a laborious life and a meagre return.

In the United States the medical school have diminished from 162 to 79 in the last twenty years the annual graduates from 5,747 to 3,862, the enrolment of students is 33 per cent less. A study of 283 rural counties in 41 States by Dr. W. A. Pusey shows the average age of physicians to be 52 years, only 9 per cent were graduates of the last ten years, no recent graduate has gone into those counties in that period. And the same authority discloses that in 162 of these 283 rural counties 431 non-medical practitioners have settled as against 197 physicians. This striving after an abstract ideal has imposed a choice between a moderately qualified physician and a practitioner with no qualifications whatever.

Few teachers in Canadian schools teach for pay. They are impelled to hand down the tradition of medicine unimpaired and enriched to those who are worthy to receive and willing to transmit that truth in their turn. We do not feel so strongly impelled to pass that tradition to strangers who from lack of background are unqualified to receive it who come to us not for love of the Art but for love of gain, and leave the country with what they have won.

This migration is controlled from the United States, and

various self-constituted bodies assume that control. They attempt to control our education by specifying what and how much we shall teach, under penalty of excluding our own graduates if we are recalcitrant. Up to the present year the control was even more specific. Inspectors were sent to our schools to ascertain that they complied with those regulations. They classified our schools. When they had filled the schools of the highest class, they raised another to first rank and that school was promptly sought. If a school refused to be inspected it was given no standing. American students would not come to it, since their future employment in their own country depended upon the inclusion of their place of graduation upon a technical list. Our own students would deliberate before joining that school since they would be forever debarred from practice in the United States.

Happily this control has been relaxed and the inspection is at an end. Categories of Canadian schools are no longer published. All are presumed to be in the highest class. The event is now only of historical interest, and it is recorded merely as a warning against the future. This happy result I surmise, is due to the persistence with which our own Dean has represented to you the impropriety of the procedure, and your willingness to apprehend a situation when it is fairly presented. Possibly the excellence of the Canadian schools is now taken for granted and the increasing excellence of the smaller schools may in a measure be due to some good in that inspection no matter how distasteful it was at the time.

The pressing demand by Canadian students makes foreign classification a matter of less concern. One Canadian school always seemed to do very well without membership in our American association without foreign classification without American students. Queen's classes are full to the limit with Canadian students alone. The Dean affects not to know in what category the school is placed and his unconcern is so marked that he does not take the trouble to inquire. He surmises however that Queen's has been placed in the highest class since this year he received application from one hundred American students mainly from the city of New York. He accepted one only on the ground that his grandfather had been born in Ontario.

The final weapon in your hands is your law that the graduates of Canadian schools which do not accept your methods will be denied the right to practice in the United States. Reprisal is dangerous but we must if we cherish our ideals face that threat and proceed to examine its implications. In that event we would be left free to bestow our education upon our own students. You would be compelled to educate your own. To educate your students is of no advantage to us. Each student costs us two thousand dollars more than he pays. And if our graduates are restricted to practice in our own country, in our own Empire in the world at large to which they have now free access we shall be the losers. It is conceivable, too, that your people will come to us for surgical treatment. They are already coming in vast numbers for treatment of a much more trivial kind. From its special situation McGill remains free to all students, provided only that they come with a natural aptitude, industry, and love of the Art.

The value of an inspection depends upon the nature of the inspection and the persons who inspect. The inspectors of our hospitals are young persons without other experience. They have never taught never operated, never come into living contact with the sick. They are in the precise category of employees of a commercial agency which gives a rating to commercial firms. They have their printed questions their routes their daily routine. They must report every night their whereabouts and their doings for the day. They are sharply checked by telegraph if there is any omission. "Accept organization"—that is their cry with the fanaticism of a trade unionist or the fervour of an evangelist preaching salvation.

These inspectors will enter the Royal Victoria Hospital, for example, and demand that all the medical records be exposed to their view. And that great institution complies with the demand. Still more, these young persons undertake to inspect institutions and comment upon records conducted and written in a language which they do not

understand. From this it will be an easy step, in the name of uniformity, forbidding us to teach and record in French.

We in Canada have nothing to conceal. Our medical teaching and practice, English and French, is, and has been for a hundred years, equal to the best in the world. We never descended to the degradation of issuing diplomas for money. Those who desired such were compelled to go to the United States. We never had proprietary schools, save in the sense that the teachers taught without reward, and at the end of each year paid the deficit. But these schools have long since become an integral part of the universities as medical faculties—McGill in 1829, Trinity and Toronto in 1905, and Queen's in 1892. It was a settled policy to appoint professors who gave their full time to special subjects. Prior to 1910 McGill had nine such heads of departments, Queen's had a full-time professor of physiology in 1892, of pathology in 1894, of anatomy in 1903. The progress in other schools was equally marked, and therefore we might properly demand that inspection be performed under our own sanction and not by alien assumption. A man of honour will not object to having his house searched, but the search must be conducted under the warrant of law, and that law must be of his own making.

So that nothing be left unsaid, there is one thing more. The Council of the American Medical Association in Chicago maintains a register of all matriculated students. Each year they send to all American and Canadian schools a form upon which the record of every student is to be given. When these returns were first made the students received a generous supply of advertising "literature" from the United States. The system is now more perfect; the names of rejected applicants also are inquired for. Business enterprise may go too far.

Our existence as a profession, peculiarly protected by law, depends upon our service to the public at large, not alone to the rich, and the indigent who fill the hospitals. To honest men medical service has become a luxury. They are already doing without or drawing help from irregular channels. Partly as a result of professional propaganda, to the sick the proprietary purveyor is denied, to the aged the comfort of alcohol, and to those dying in pain the solace of opium. In the end, they may sweep away those privileges with which we have surrounded ourselves, medical practice will be left free to all who care to engage in it, subject only to the restrictions of the common law, the public left equally free to choose the best they can afford. That is the remedy against the theoretically standardized hospital and medical school, and against any profession when it becomes a hereditary caste. It is an outworn convention that a profession is empowered solely in the public interest.

I am well aware that American inspectors are making a resolute effort to enter upon our farms, dairies, and factories to report upon costs and results. Upon their report will depend the duties to be levied on that part of their product entering the United States. Education, learning, and skill are not so easily assessed.

In the United States the supreme law is their own prosperity, and their people are under the delusion that their prosperity means the prosperity of the whole world. No man can live for himself alone, no nation either. Isolated though they are, their domestic legislation concerns the whole world. One of their domestic prohibitions bred a race of native smugglers who, in pursuit of their profession, broke our revenue laws, corrupted some of our officials, directly destroyed our Government, and precipitated a constitutional issue which gravely affects the whole Empire.

To meet the necessity of the moment, you framed certain medical regulations. The need passed. A new situation arose. But the rules in the meantime had become embedded in State or Federal law, and you were powerless to change them. We abandon our regulations when they have fulfilled their purpose, or when we discover we were mistaken. If we find too much difficulty in changing our laws, we change our Government. Last summer we had three successive Governments in eighty-five days. We refuse to be enslaved by laws which we ourselves have made. You must not, therefore, be surprised if we should change the regulations

and laws by which our medical education and practice is governed. Still less need you be surprised if that change should not conform with the methods you have devised for us.

The American method in surgery is an application of the American method in business—uniformity, a single standard, mass production. The desired end is "efficiency." That also is our aim, but we do not believe that the terms of business are valid in the realm of mind and heart. We believe that success in surgery must come through individual freedom, fresh observation, natural aptitude, flexibility of technique, and adherence not to methods but to principles alone. This mechanical method would be, and now is, fatal to us. In the end it will prove fatal to surgery in the United States as well. It was method destroyed medicine in Alexandria, in the Byzantine Empire, in Arabia. The Galenic method lay like an incubus upon the world for a thousand years, until the surgeons of the Italian and French Renaissance discovered anew the principles of Hippocrates. It was finally destroyed by our own Harvey and Sydenham.

The simple answer to my protest is the value of team work. It is proper to affirm that the value of a team depends upon the driver and the consent of the team to be driven. It also depends upon the foothold. I have watched a team of twenty-two mules struggling with a gun. The more they pulled, the further they sank in the mud—and the gun never stirred.

Under this inhuman system a new kind of physician and a new kind of surgeon have been developed. The physician studies only a part of the patient, the patient is to him nothing more than a series of microscopic slides or chemical solutions. The surgeon knows the patient merely as an arrangement of typewritten cards. He sees him for the first time unconscious on the table, when he comes like a masked executioner to complete the sentence of the judge. Physician and surgeon become sheer empirics, working upon a narrow experimental basis, without philosophical conceptions or even a scientific hypothesis of disease. In pernicious anaemia they will remove the spleen merely because the removal of the spleen appeared to give relief in other cases diagnosed as pernicious anaemia. This practice is far removed from the old injunction to place the patient, and his friends, and *παρά τα ἔσθαι* in train for his recovery. Surgery and medicine, science and practice, can exist only in one mind. When these are divorced, they become, as Mr. Squigg said in another sphere, scientific mules condemned to a stupid sterility.

This domination of the Art by science is not new. Before the protest in Paris in the latter half of the fifteenth century, there was a powerful body of *medicus reclus*, who would not visit or see their patients. The scientists contented themselves with an examination of the patients' excreta, brought by a servant, and sent the proper prescription. They feared lest a look upon the sick man might disturb their diagnosis.

It may be true that "treatment can be logically based only on an accurate knowledge of the nature and cause of the disease," but disease has a logic of its own that is deeper than the mind of the laboratory. It is a physician, not a logician, the patient demands. The clinical laboratory mind stops short when a manufactured name is given to a disease. The patient is not interested in diagnosis. There is not a drug in the Pharmacopoeia nor a method of treatment in all therapy which was not freely and successfully employed before modern methods of diagnosis were imagined. Artificial immunization, the destruction of one organism by another, the use of vaccine against trypanosomes, was practised by races which had not yet emerged from a condition of savagery. Diagnosis is merely a preliminary intellectual process in the mind of the attendant. Prognosis and cure is what the patient demands, and in the field of prognosis the quack beats us on our own ground. The *Prognostics* of Hippocrates demanded seventy editions in medieval times, the important work of Sir James Mackenzie in heart disease had to do not with the past or even with the present condition of the patient, but with his future career. Our own James Stewart possibly went too far in his teaching never make a diagnosis unless you are compelled to. Professor

Oertel says the same thing when he suggests that the diagnosis be left to him, after he has finished his work at the *post mortem* table and that the physician concern himself with the cure.

An ideal may be transplanted, a system cannot. The one may grow, the other will perish on alien soil. And these two countries are alien the one to the other. The resemblance is obvious but superficial; the difference is profound. We both speak a language which is so similar that we understand each other when we converse, unlike indeed we speak French, which one-third of us do. The difference is as profound as this: we are Europeans, you are Americans.

There is a Canadian surgery. For five years we put it to the test on European fields. In virtue of its flexibility it adapted itself to every need. Standard surgery is a civil surgery. It demands a wound made by the surgeon himself at his own point of election upon a surface which he perceives in circumstances which he controls. When it becomes too much it hurls itself down utterly at the first touch of war. It hurls down equally when surgical aid is demanded by the dweller in the country at the hands of the general practitioner.

Then the standard of measure varies with the thing to be measured. A microscopist uses the micro-millimeter, a land surveyor uses the link and chain. Our surgeons have surveyed the field of war and the infinitely little field of the laboratory. They have operated in the shining theatre with more than Icarian scrupulosity; they have performed the most delicate and profound surgery in field ambulance and casualty clearing stations upon trestles in huts or open tents with only the heat from a brazier and not even running water. Their results were admirable for all the world to see.

Those surgeons trained by reality are to be found in every village in Canada. Their virtue is within them. They bend their means to their needs. They have erected little surgical centres where the surgery is or the first rate because it is done by a surgeon who is himself of the first rate. Suddenly he discovers that some outside power has decreed that his hospital is only of the third rank and this decree is published to the world. He then in the public mind has become a third class surgeon. Persons who can afford an operation can afford to travel. They slip across the border, especially in the West to an

A hospital. This surgeon himself finding his practice destroyed migrates to an 'A hospital' when he becomes first class once more and drives in a closed car.

In the first place even from Montreal patients slip quietly across the border for treatment but for quite a different reason. The American method is one of publicity. We have forgotten the Hippocratic injunction that things seen and heard at the bedside shall not be disclosed. We have become garrulous; the private concerns of a patient are now a matter of common gossip. A sick person is entitled to his own reticences. If he seeks surgical relief for a trivial ailment, the details are published on the bulletin board of the operating room for all the world to see and hear. A rich man is not now sure that the old confidence of a private consultation will be respected. Even a rich man may have creditors. Next morning his blood pressure, the diagnosis and prognosis are discussed in his bank and by his associates and subordinates who may have designs upon his place. He cannot afford this publicity. He seeks advice where he is protected by the obscurity of a strange place.

Such obscurity will soon be difficult to obtain. Every standard hospital is in the way of being equipped with a machine for recording each stage of the operation and doubtless a "clo-cup" of the operator as well. At this moment the main body of the American College of Surgeons is hearing how that may be done from Will H. Hays who is described ecstatically as the mogul the czar the dynamo of the moving picture world.

Those little centres had their medical societies which continued to form district meetings which by further conurbation formed provincial societies, and these in turn a Canadian Medical Association. This blow at the small hospital a blow struck merely on account of its smallness strikes at the foundation of our whole medical fabric. This

is a new reading of the old fable: a well meaning elephant who insists in the hatching of eggs in more familiar terms, a vital child overlain by a stupefied nurse.

It has always been in the individual teacher, usually in the small school, in the small hospital that medicine has sought refuge from the dead hand of a system. Boerhaave in a ward of only twelve beds at Leiden established modern clinical medicine in Europe. In addition he gave four lectures a day on botany, chemistry and the institutes of medicine. He was not a generalist. Sydenham was content with the simplest form of practice, he belonged to no faculty and was lit in no school.

It would be easy to imagine your president, W. W. Chipman taking up his residence in Kentville—an equally famous surgeon has retired to that charming place. According to your method of reasoning he would automatically become lower than a third rate surgeon. Indeed, Clarence Webster at one time assistant professor of obstetrics in Edinburgh afterwards professor at McGill, and again in Chicago had the good sense to retire to Shediac. Your instructors would be compelled by your own rules to classify him with the local midwife. And if Sydenham came to practice amongst us he would be refused a licence, although Hippocrates might be admitted to study on the ground that he had a preliminary qualification in Creel. Sir William Osler once congratulated himself on being admitted to Johns Hopkins as a prof. He could never he said, have gained admittance as a student.

The inherent fallacy in the American method is the assumption that all graduates from certain schools are qualified for the highest posts and that all graduates from certain other schools are equally disqualified. The relative classification of those schools by the present method of mechanical inspection is and must be defective. It is fatal. Therefore the system must break down. It has broken down. Appraisalment there must be but that appraisalment must extend beyond the school to the student possibly even to the teacher and it is the student himself who must make that preliminary estimate. In the same school there are students of varying capacity depending upon their natures physique training breeding manners and culture. They should be left free and encouraged to choose the field in which they will practice.

In every school the true aim must be up to the level demanded by the needs of the student who aspires to general practice. If it stops at that the school is a poor school. It must rise to heights which can be reached only by the rarer spirits. That level can be maintained and those heights disclosed by the same teacher in the same lecture—if he is a real teacher. Each student will follow as far as he can and be so insulated by those who can go the furthest. I pause long enough to repeat a remark of your president—that every practitioner will confess that he has no aptitude for certain forms of practice but is never heard to confess that he has no aptitude for teaching.

In England there is no entrance into the general field of practice. From that field various paths arise and each path is barred by a rigorous and just examination. Here we hold all graduates of certain schools to be equally qualified. There is no further mark unless it be the letters F.A.C.S. appended to one's name but I have not sufficiently investigated the process by which that distinction is achieved.

The most modern scientist I suppose will admit that a medical school has something to do with qualifying young men for the practice of medicine. The right of decision has long since been withdrawn from the medical schools. For Canada that right has been conferred upon the Dominion Medical Council. Their examiners are experienced in every department of practice and teaching. From their last report it appears that the largest percentage of graduate considered to be qualified—that is not a menace to the community—came from the four schools to which first class rank had been denied. The order of merit was in the inverse ratio to the equipment and size of the school.

In this race for magnitude and pomp the hospital, too, is erected from its foundation, a place where simple charity is dispensed and the recipient properly compelled to bear the stigma of charity. To avoid that stigma is the greatest

incentive to providence, prevision, and self-reliance. The improvident poor and some of the parsimonious rich now demand free hospital treatment as a natural right. The profession is exploited, the stream of charity fails, the poor will suffer, it is the poor who always suffer in the end from new taxes, such as those which are now so glibly demanded for these elaborate hospitals. Those who imagine the "efficiency" of a "standard" hospital have never witnessed the real efficiency of an aid-post, a field ambulance, or a private dispensary.

This is the efficiency prescribed by W. G. M. Byers in his protest (*BRITISH MEDICAL JOURNAL*, July 1st, 1922), that a graduate must be able to do a certain number of things before he is let loose in the community. His fitness is to be judged by what he can do, not alone by what he can write or say. And he must complete the thing, fifty per cent is not enough. What those things shall be does not pass the wit of a faculty of practitioners to specify. Beyond this limit, he may do and know as much as he can master. That is medical education.

We have developed a new dogma, *Ex hospitalis nulla salus*—no corporeal salvation without the hospital, not even for the parturient woman, who is persuaded that conception is a calamity and parturition a disease. The general practitioner has fallen into desuetude, especially those admirable physicians rationally qualified and trained by experience, whose dispensaries were free to all for a fee that was within the means of every self-respecting person. They detected disease at its very first onset. The patient who has fought his way into the wards is already dead. We have forgotten our humble, though lawful, progenitors, the battle surgeons.

Last year, in the Montreal General Hospital, the first hospital in America to admit students into the wards, the daily average number of patients was 329, the daily cost of each public patient was 3.68 dollars. If the items of taxes, rent, depreciation, and medical attendance were added, the cost to the community would be ten dollars. To serve these patients and those attending the outdoor department, a medical staff of 160 persons and 175 nurses is required. These public patients paid more than one-third the cost of their maintenance. In the Hotel-Dieu the cost was less, in the Royal Victoria it was more.

In other days the pride of a hospital was in the number of indigent who were relieved, now the boast is of the amount of money that is extracted from them by a band of paid inquisitors, known as social workers. It does not appear from the last annual report of the Montreal General Hospital what was the daily average of beds occupied by patients from which the hospital received nothing from any source. The number is so small in every hospital that the idea of charity has practically disappeared. And if the claim is made that the hospital is now "run on a business basis," it is fair to remark that a business which expends upon salaries and wages the sum of 205 thousand dollars out of a total "turnover" of 607 thousand dollars, with an operating deficit of 235 thousand dollars, is a badly managed business.

I am not saying that this hospital is unique. It is merely one of those that have been standardized to American methods. There are not enough people in Canada to support this expenditure either by private charity or by public tax. In the United States it may be different—they have sources of revenue denied to us. We must return once more to the simple way of charity unless we are willing to assume these inflated hospitals as once we assumed the equally bankrupt railways.

There is between us a conflict deeper still, the ancient Conflict of Studies. The American method of teaching is the experimental. It assumes that the student can understand nothing he hears with his ears. He must be shown a picture of a thing, as if he were a deaf-mute. I speak with knowledge, for in the past ten years I was present, as a spectator, at four lectures. I shall give a summary of each.

The first was upon the structure of the Universe. The eminent physicist, when he had occasion to mention the term "water," held up a glass. As water is transparent, I was compelled to take his word for it after all. The second lecture was upon "Relativity." When the eminent

mathematician had occasion to mention "the man in the railway train," he drew a rectangle on the board with an upright line inside. At the end of an hour he had not come to the explanation, and I went home to read a book for myself. The third lecture was upon "Cults rival to Christianity." The eminent classicist had occasion to mention a place in Persia, but it was beyond the limit of his science, and he pointed to a spot in the black void. At the fourth lecture the eminent astronomer came provided with the model of a planet, but he neglected to take it out of his pocket.

"Show me, not tell me," is the "slogan" of the experimentalists. This is the old and vulgar demand for a miracle. If students will not hear their prophets, neither will they be persuaded though one rise from the dead. Or, in the more homely words of Isaac Todhunter, from whose books I learned what mathematics I know: "If a student does not believe the statements of his tutor, probably a clergyman of mature knowledge, recognized ability, and blameless character, his suspicion is irrational, and manifests a want of the power of appreciating evidence, a want fatal to his success in that branch of science, which he is supposed to be cultivating." Under this experimental system it is folly to read, an offence to remember.

A real experiment is a valuable product of the human mind, requiring knowledge to invent and ingenuity in performing it. When Augustus Waller demonstrated at McGill for the first time that electrical currents are present in the skin of a dead codfish, he performed an experiment. The thing was done once and for all time. The teacher who repeats the operation before his class is making not an experiment but a repetition of an observation made a thousand times before. It is now pretty well understood that the air exercises pressure. To allow a student to work the handle of the air pump would impress his mind to watch a professor work it is not so convincing. I doubt the educational value of the performance. The student may take more interest, he would take more interest in football, but the extent of his interest is no true measure of value.

For the true place of experiment let us ask of the mathematicians again. The marvellous power of modern computation depends upon a machine, known as logarithms, invented by Napier in 1614. Four years later, Gunter designed a still more mechanical "line of numbers." Improvise, Oughtred pushed the device to its present point of perfection. It is known as the "slide-rule." Of the machines for avoiding mental labour in computation no other is of equal value. And yet the inventor used it in secret for ten years. When he was finally reproached by a friend and pupil for concealing so useful an invention, he enunciated for all time the true relation between the machine and the mind: "That the true way of Art is not by Instruments but by Demonstration, and that it is a pernicious course of vulgar teachers to begin with Instruments and not with the Sciences, and so instead of Artists to make their Scholars only doers of tricks, and as it were Juglers, to the despising of Art, losse of precious time, and betraying of willing and industrious wits into ignorance and idleness, that the use of instruments is indeed excellent, if a man be an artist, but contemptible being set and opposed to Art. And lastly, that he merit to commend to me the skill of Instruments but first he would have me well instructed in the Sciences."

The first claim on behalf of routine experiments is that they save labour. The real reason for their employment is that they save thought, and mental exercise is the severest form of work. But the student who has been taught to rely upon experiments alone becomes the practitioner who relies blindly upon instruments. He allows his mind to atrophy, and is helpless without them. He has become a mere mechanic, useless without his tools.

And yet this is the occupation in which students are compelled to spend two precious years in institutes, colleges, and even in some universities, watching routine experiments in physics, chemistry, and biology, performed by young instructors who may be only a little less illiterate than themselves, peering into microscopes, when the large world of nature lies outspread. They would be better occupied

in their own homes in contact with the great minds revealed in books, especially with the great minds of medicine from Hippocrates to Osler.

With this reserve, I am careful to add full praise to that large class who learned from Harrington and Ruttan, pathology from Johnston and Adams, geology from the rocks, and botany from the plants of the field, as taught by Sir William Dawson and Frank Adams, and in Toronto by Sir Daniel Wilson, whose very whiskers suggested the immensity of his theme.

In this audience there are exquisite physicians and masters of surgery, yet I doubt if there is anyone here pre- or excepting myself, who can write on the board the formula for a simple substance as phenolphthalein who can say if the sun goes around the earth or the earth goes around the sun, or can explain why the moon varies in appearance on successive nights. Why, then, should students be expected to know so much before they begin the study of medicine?

The next precept is, "Let the student solve his own problems." That was the way of Pasteur and Harvey—no hired man for all but the chosen few, it means the abnegation of the professor. Is teaching then, of no value? And if a student is to solve his own problems, he can solve them at home without spending seven years in the university.

In the *Bulletins of the Association of American Medical Colleges* although you will find in them strange form of procedure, and, as Maurice Hutton says of Plato, every kind of educational non sense you will find also a deep distrust of the rigid and uniform requirements of the pre-medical years. They are looked upon as "order," a nuisance, a penalty, a "barren stretch of wilderness" imposed upon the aspirants to the study of medicine. They are regarded also as "a failure to motivate prospective medical students."

In the *Bulletin* for July a resolution passed unanimously at the Christ Church meeting of 1925 is quoted with approval. According to that resolution, the Association and the State licensing boards are to be asked to permit as an experiment "for a medical school to modify the curriculum in any way they think desirable, in order to get free from the bonds which now bind and hamper them." My plea is that Canadian schools be permitted to undertake that experiment. No one knows who it was that constructed this rigid curriculum. No one pretends that it is best for either country. The utmost claim is that it is identical for both. One may say of it, as Henri de Mondeville said of Galen, "I do not suppose God exhausted His power in creating it." The wisest of the Americans are also in revolt. That revolt began with us. My desire is to give to it duee on and force.

Pushed to a conclusion, the advocates of the experimental method would content themselves by pointing out the professors and assigning their names as they walk in the university grounds. The experimental method may be mental labour. That is not the end of education. To a stupid person an experiment is as conclusive as a lecture or a book.

These various American foundations, colleges, and universities by their very fluctuations performed a task of incalculable good in their own country. They destroyed the mercenary school and many other evils that were disclosed in the survey of twenty years ago. It is for them to decide when their work is done. It may well be that the time has come for them to take off their whips and restore freedom to the universities. In Canada too their operation has been of some advantage. They have freed us from our complacency but the time is such come when we must be left free to build according to our own needs.

Canadian medical schools suffer in turn from the various provincial boards. Their rules and regulations are really identical in respect of time and course of study. They imitate and copy one another until they have produced a mass of legislation in which no one believes which not only approves. By a process of evolution and accretion they have created a fossil, which might be correctly labelled "unreassuring arbitrary ultimate." And that is the dead hand under which the medical school and the medical student lie. This rigid curriculum is the death warrant

for any vital aspiration in the medical student or teacher. It emerged from the chaos of the scientific mind.

The origin of evil has always been a perplexing problem. The first instinct is to assign it a place without one's own borders. After yielding full credit to the United States as a possible nidus, let us inquire in how far it has arisen de novo amongst ourselves, or is the result of a universal cause. Let us begin with the valid experience that all practice has its origin in a pre-existing theory.

The theory of the macrocosm and microcosm devised by the Greeks, developed by the Arabians, and reaffirmed by Dante, was the central dogma of medicine so long as Graeco-Arabist influence prevailed. Even Darwin, when he attempted to assign a general term to the human body, could find no better term than "microcosm." The Arabist treatment of wounds by inactive compounds and caustics survived all the masters of surgery: Bruno, Huh of Lucca, Theodoric, Henry of Mondeville, even Pare himself, and finally came to an end in the practice of Lister.

Parallel with this, from an even greater antiquity ran the doctrine of the four elements, each composed of four primary qualities which had their corresponding qualities in the humours of the microcosm. Medical study then became an affair of rhetoric rather than logic, physiology, and pathology. Even Vesalius could not free himself from those influences. He failed to discover the Galenic vessels between the vertebrae of the heart. He was not bold enough to do what the existence he described him as "invisible." Harvey made no such compromise. He followed where sound argument and ocular demonstration led.

In such more modern time, alternative and equally binding doctrines came into force. Governed by Newton's laws, a man University was constructed like a model in the patent office or a glorified United States. Man himself becomes an automaton or at best an internal combustion engine run by compressed animal spirits. This Cartesian man was too simple. With the new chemistry a chemical man was created approaching very close to the modern concept of a phenotype gradually developed from the protozoon by mutation of ids and genes but still composed of atoms dissolved in water. One who now aspires to write on medicine must learn the jargon in which medicine is written.

By the premature application of such partial principles a few and scientific medicine is always built up, but medicine, just as it is at the point of becoming scientific, falls into ruin. On one occasion Sidenham's was the hand that cast it down. "You cannot imagine how far a little observation carefully made by a man not tied up to the four humours, or to sulphur and mercury or to acid and alkali will carry a man in the curing of disease." Sidenham began where Hippocrates stopped. He was not a scientist. He was a physician. The one is the antithesis of the other. He abandoned hypothesis. He was less concerned with experiments than with facts that arose from actual observation of the processes in health and disease.

Once more and in our own time, the teaching of medicine has fallen into the hands of the scientists who are so dominated by the doctrine of evolution that they have little thought for the thing that has been evolved and less still for the process of development which is known to physicians as disease. In their own sphere they have attained neither to fixity of principle nor to permanence of indecision. They vacillate from moment to moment like a cow walking. They cannot teach because their boast is that they do not know, that they are still learning. Their aim is to convert their students into agnostics like themselves. These are the men who construct the curriculum for medical schools. Their mind is one. The result is the same. That is the ultimate origin of the evil. The laboratory is the temple and the one who sits in the temple soon comes to show themelves as gods.

In our own time, happily, teachers and practitioners have arisen who are strong enough to break those bonds and bend the sciences to their needs. They did not disdain tradition and learning like Porcarius who began his career by burning his books and declaring that Galen was less to him than his shoe-buckles. Sir William Osler as a teacher,

and Sir James Mackenzie as a practitioner, will serve as examples of this new courage. Mackenzie, like Sydenham, fell back upon unaided observation, and disclosed heart disease in the strong light of experience. Nor did his courage go unrewarded. After twenty years of Bunley porridge, he sat turtle at the Athenæum, clutched his cup in Harley Street, he himself had fished the murex up.

Looking more closely at the problem, the evil lies within our own Faculties. The scientist has gained too much control. In the intervals between the repetition of experiments, made by original investigators, to prove what every one knows, he has ample leisure to enforce his methods upon medical teaching. The physician is preoccupied with the sick and dying. The surgeon is devoted to his technique, and in the work of his hands forgets to employ his mind. Both are meticulous. They allow the scientists of the laboratory and of the clinic to dominate the course, and the student falls into the gulf that lies between science and practice. In lucid moments the laboratory mind is assailed by doubt of the possibility or wisdom of attempting to convert the medical student into an abstract scientist. It then falls back upon the "cultural value" of the process, but further doubt must be created by personal introspection into the recesses of that mind itself. Life is too short, the Art too long. The student is wasting his time upon preliminary sciences, as a carpenter would be wasting his time upon the botany of the wood he employs, as a chemist or a physicist might be wasting his upon the further antecedent sciences of alchemy and astrology.

The theme of the present thesis is a plea that the power of these associations, boards, faculties, laboratories, and elective colleges be broken, that freedom of teaching be restored to the universities and to teachers who have the precious gift of teaching, that the present curriculum be examined with that freshness of mind which, according to the scientists themselves, should be applied to all sacred writings. This is merely their own plea for experience in the face of authority.

But the authority of these various provincial boards is already shaken from within. The Canada Medical Act permits the provincial boards to dispense with examinations. One province, British Columbia, has eliminated the

local board, and depends upon the Dominion Council. Another province, without any formal self-denying ordinance, but unselfishly and for the general good, is sending medical graduates in increasing numbers direct to the Dominion Council for licence to practice. That body is growing in favour by reason of its professional strength and freedom from technical influences. It is a new creation, it is not entrenched, it is close to the wide scrutiny of Parliament, which has never been impressed by pedagogic assumptions. This Council may in time become an instrument of freedom to the universities.

The winning of my old master was "Hesitate before you begin an operation, once you have begun you must not stop your hand." I am newly done. You have borne in patience, without the anaesthesia of flattery. All nations are admirable in their own environment, they develop ideals and create methods which are inevitable for themselves alone. Their culture is powerful only so long as it remains free to the world. The attempt to enforce that culture, those ideals, those methods over their own borders creates hostility, always ends in disaster to themselves, and frequently in disaster to their neighbours. That was the fatal error into which the Germans fell—a lack of sensibility to the feelings, emotions, beliefs, and prejudices of other peoples—they themselves being like you, so naive, so amiable, so ingenious, so convinced, and sincere.

Respect for boundaries, national, physical, social, and intellectual, is the prime condition of peace between friends, families, and nations. The more closely these units are related the more scrupulously must that respect be observed. Therefore, I beseech you, do not press upon us too closely American methods in our medical education.

And yet, it does so often happen that the evil we deplore never comes to pass. Nothing is so bad—or so good—as we expect. A pine tree does not grow up to the sky, nor a man's whiskers to the ground. Your president this year is a Canadian. Since I came into this room, I am informed that your president-elect is George Stewart, a Canadian too—that is, if for the purpose of my theme, and following immemorial usage, I may ascribe the glory of the Maritime Provinces to Canada at large. It may therefore be that after all nothing will happen, or, indeed, that we shall persuade and enable you to accept not our methods but those ideals which we have inherited.

## The Profession of Medicine.

### INTRODUCTORY

THE main object of this Educational Number of the BRITISH MEDICAL JOURNAL is to be of assistance to prospective students and their parents. It is largely a guide to the steps that must be taken and the studies that must be pursued in order to become a registered medical practitioner. It contains also a section on post-graduate medical teaching in Great Britain and other sections addressed more particularly to those who have just qualified and are considering what path in medicine they should follow. The details given are founded for the most part on official information, and are mingled among the customary lines. As in past years we take occasion in this introductory article to review some aspects of medical study and practice to-day, in order to put the situation before those who think of devoting themselves to medicine, and thus help them to gauge their fitness for the calling and the prospects it holds out.

Our opening article this year is an address on American methods of medical education, delivered in Montreal last autumn by Sir ANDREW MACFARLANE, Professor of the History of Medicine in McGill University. While his outspoken criticisms apply for the most part to conditions in Canada and the United States, much of what he says has to do with medical education everywhere, and his words can hardly fail to stimulate thought among the wider audience to whom we now present them. His thesis, in effect, is

a plea for greater freedom in teaching and for a thorough examination of the curriculum in the light of modern requirements and ideals. The problems of medical education are not quite the same on each side of the Atlantic, but it may be that we, too, would be the better for a few home truths about the "dead hand," and need a warning against "efficiency" and "standardization" when these are imposed upon a country from outside.

The intending student will find in subsequent pages an account of the course of training required of him, the places where it can be obtained, and the universities and other licensing bodies which test the knowledge gained and confer degrees or diplomas entitling successful candidates to become legally qualified medical practitioners.

### THE GROUNDWORK OF MEDICAL STUDY

"Three principles of all professional education seem to be fundamental," wrote Sir Clifford Allbutt. "First to secure a good general education, secondly, a good scientific education, thirdly, a good technical education." Upon the first of these the second and third largely depend. As for the second, no one can overstress the value to a doctor of a thorough grounding in the basic principles of science, for medicine is in its foundation on science. The temptation to take short views and short cuts is very

<sup>1</sup> The Training of the Medical Student. BRITISH MEDICAL JOURNAL, September 2nd, 1922, p. 407.

strong in the early years of the medical curriculum, but no greater can be made than to work at any branch of preliminary study as though it were something to be thrown aside and forgotten when the examination immediately ahead has been passed. The student of good intelligence who makes it his aim to grasp the principles of each of the fundamental sciences need have little dread of examiners. In mastering the principles he will find that the larger details take on new meanings and a new interest, and so are fixed in his memory. Moreover, the preliminary sciences give a drilling in exact methods, in precise manipulations, and in vigorous reasoning which will bear immediate fruit in the later clinical part of the curriculum and prove of lasting benefit throughout professional life. The purpose of medical education is to build up on scientific principles a solid structure of practical knowledge. Students who keep this in mind will look upon "exam work" as a weakness in the foundations, and therefore as a hidden danger to the superstructure. The great anatomist John Hunter, as Sir Arthur Keith reminded us in last year's Educational Number "studied anatomy and physiology to get help in diagnosing and treating his patients. He studied dead things to understand the living and observed living things to understand the dead." A knowledge of how this body is made and how it works must provide the basis for all the more practical subjects of medicine."

#### PORTALS OF THE PROFESSION

The goal of every student is the entry of his name in the *Medical Register*, which is the official statutory list of qualified medical practitioners kept by the General Medical Council. Those who are not familiar with the system of medical teaching and examination in these islands, and with the history of our professional institutions may feel bewildered at first sight by the number and variety of ways in which admission may be obtained to the *Register*. They will see in the table of contents to this Educational Number that there are twenty-seven bodies—eighteen universities and nine corporations—which either separately or jointly issue registrable qualifications, and the number of teaching institutions is even larger. Nevertheless, although we have no single State examination in medicine—no "one portal," as it has been termed—the medical courses of the various universities and schools in Great Britain and Ireland run on parallel lines and the obligatory curriculum is much the same for all students. As, however, the individual teaching and examining bodies have different standards and requirements, the choice should be made early so that a definite plan may be followed. It is therefore important to gain some idea of the value in different walks of medical life, of the various degrees and diplomas and of the comparative difficulties they present.

All who wish to enter the profession must comply with certain conditions. These are regulated by the General Medical Council, which is a statutory body set up under the Medical Acts, a summary of its requirements is given at page 385. Many changes have lately been made in the medical and pre-medical curriculum, and this section, as well as the article on Professional Study and Examination, should be studied with care. It is the business of the General Medical Council, so far as possible to see that a suitable kind of training and the requisite degree of knowledge are secured to the student and it is the business of the medical schools and examining bodies to give the training and test the knowledge in accordance with the requirements of that Council. Every student, after passing examinations in the subjects of general education and in the preliminary sciences, must take a course of training at a recognized medical school, covering a period of at least five years, but usually extended to six years or more.

Examination of candidates as to their fitness to practise medicine, surgery, and obstetrics is left to the licensing bodies, which are of two kinds—the universities, and certain medical corporations in England, Scotland, and Ireland. The requirements of these licensing bodies are summarized elsewhere under separate headings. One of the functions of the General Medical Council, besides that of keeping the *Medical Register* and maintaining discipline within the profession is to make sure that the tests at each stage do not fall below a certain standard, and that the students examined have undergone prescribed courses at approved institutions. Successful candidates eventually receive either degrees in the case of a university or diplomas or licences in the case of a corporation, the qualifications entitle them to claim insertion of their names in the *Medical Register*. Every student as soon as he obtains his qualification to practise should at once register otherwise he cannot hold a public medical appointment, or sign any certificate required from a legally qualified practitioner (such as a death certificate), or recover professional fees in a court of law.

Holders of diplomas and licences once made up the great majority of all medical men especially in England and Wales. But universities have greatly multiplied and so many practitioners are now graduates in medicine that a student at the threshold of his career will do well to aim at a degree, though it may be desirable to take also a diploma or licence. The medical degrees (M.B., M.D. etc.) granted by the universities in Great Britain and Ireland are mentioned among the particulars relating to each university printed elsewhere in this issue.

#### COST OF MEDICAL EDUCATION

The first thing to be said under this heading is that the cost of a medical education varies within wide limits. Besides differences in the charges made for instruction, there are differences in examination fees, as well as in the fees for certificates of qualification and those who seek the higher degrees and diplomas must expect to pay more for the additional courses and tests and certificates. Again not all students, however industrious have the knack of imparting what they know to an examiner, and every setback due to failure in the examination room or to illness means added expense. School and examination fees together with the cost of board lodging clothes, and recreation, form the largest items of expenditure and to these must be added the money spent on books, microscope, instruments and so forth. Since professional education must in any case continue for five years at least (a period exceeded by the vast majority) and since the cost of living in different parts of the country varies much while personal expenditure varies still more, it can only be said in a general way that anyone who thinks of entering the profession should be prepared for an outlay of at least £1500. Something between two-thirds and three-quarters of the whole amount would probably be spent on maintenance, and the rest in fees etc., for tuition and examination. On the other hand more scholarships and money prizes are offered now than in the past at the Scottish universities bursaries are numerous and the Carnegie Trust (whose regulations are summarized at page 397) gives financial help to many Scottish students. The main thing to bear in mind is that as compared with other professions the period of training in medicine is long, and for most students costly. Further guidance on this matter will be found in the recently issued memorandum, drawn up by the Registrar of the General Medical Council, on the procedure to be followed in order

to enter the profession. This pamphlet gives much useful information, concisely arranged, including a comparative table of the cost of study and examination at the various institutions.

Medical students are not commonly the sons or daughters of wealthy parents, very often their education puts a heavy strain on a slender family purse. Hence, before setting out upon this long and exacting course of study, it is usual to weigh, not only the cost, but also the prospects. An overcrowded curriculum would be hard to face if all that could be discerned at the end of it were an overcrowded profession. Without forgetting the adage, "there is always room at the top," the youth and the girl of to-day, when reckoning up their chances in any calling, will wish to know the probable numbers of their competitors for the work that is waiting to be done.

#### THE NUMBERS OF MEDICAL STUDENTS

One effect of the war was a great increase in the number of medical students, both men and women, but especially women. The climax was reached immediately after the Armistice. The following brief survey of the position should be read in conjunction with the note and tables printed at page 385 on the numbers of registered practitioners. More new students mean more new doctors five or six years later.

In the thirteen years before the war the annual entry of medical students in Great Britain and Ireland averaged about 1,400, during the war period, although many left to serve with the forces, the whole number studying in the schools grew steadily larger. In 1914 the entries rose to 1,600, and in 1915 to 1,918, in 1916 they were 1,875, in 1917 they rose again to 2,150, and in 1918 to 2,253, and in the following year, when demobilization was in active progress, as many as 3,420 new students were registered. After 1919 the number of entries rapidly fell. They were 2,531 in 1920, 1,808 in 1921, and 1,933 in 1922. In 1923 the entries dropped to 545, and the reasons were discussed by Sir Donald MacLister in his presidential address to the General Medical Council. He suggested that the sudden falling off was more apparent than real, and attributed it to the introduction of a pre-registration test in elementary physics and chemistry. This has been borne out by the figures for the three following years. In 1924 the entries were 1,043, in 1925 they were 1,070, and in 1926 they rose to 1,260.

The recent decline is an advantage, because excessive entries of students, if they go on long enough, lead to overstocking of the profession. In the past five years the numbers of new practitioners have greatly exceeded the usual pre-war figure of eleven hundred or so. Registrations in 1922 numbered 1,963, they rose to 2,482 in 1923, and to 2,796 in 1924, in 1925 they were 2,570, and last year 2,120. The large additions to the profession in recent years brought the total number of names in the *Medical Register* up to 52,614 at the end of 1926. This is ten thousand more than the figure for 1914, and the ratio of doctors to population is now considerably higher than at any previous time. It is true that the scope of medical practice has widened, and fresh openings for functional work have appeared, but there must be limits to demand, and the supply of new practitioners ought to outstrip the medical needs of the community. The regulations of the General Medical Council, which came into force in 1923, were drawn up for another purpose, namely, they should incidentally do something to keep the entire profession within manageable bounds. On the whole, it may be said that, with these of good average intelligence who are not afraid of work, the prospect in medicine to-day is quite favourable.

#### CHOICE OF A CAREER IN MEDICINE

The student, having passed all his tests and placed his name on the *Medical Register*, becomes a member of the profession and assumes the privileges and responsibilities that go with legal qualification. But the final examination is only the gateway into a wider field of training and experience. Education must continue throughout his career, a good doctor remains always a student. As an introduction to practice of whatever kind, nothing is so useful as a year or more spent in junior hospital appointments, and all who can afford the time should look upon the holding of such posts as a most profitable investment. If his mind has not been made up already the young practitioner has now to consider in which branch of the profession he can best exercise his abilities. The choice is very wide. Among the great variety of paths open to men of different tastes and talents are general practice in town or country, Government service at home or abroad, including, of course, the medical branches of the Navy and Army and Air Force, and the I.M.S., public health appointments and other administrative or official posts, institutional work, such as that of the asylum service, and special work in scientific research and teaching, or in one of the many subdivisions of clinical medicine and surgery. Most of these careers are discussed in some detail in the later sections of our present issue, but a few words may be said here about general practice and the work of a consultant or specialist.

Useful information and advice on such matters will be found in the *Handbook for Recently Qualified Medical Practitioners*, published by the British Medical Association. This comprises articles on the main openings for members of the profession, on some practical aspects of medical work, especially the legal and ethical aspects, on registration and the privileges of practitioners, on medical work under the National Insurance Acts, on post-graduation study and special diplomas, on specialization and consulting practice, on the fellowships, scholarships, studentships, prizes, and research grants open to students and practitioners, and on the important subject of individual medical defence. The section on practical aspects of medical work, specially prepared for the second edition, will be found of much value to all members of the profession. It embodies a great deal of advice on professional conduct in general, on medico-legal difficulties of common occurrence, and on the relations between doctor and patient and one doctor and another.

#### GENERAL MEDICAL PRACTICE

This field of medical work has hitherto been, and still is, the destination of the great bulk of students—perhaps as many as 75 per cent. The life is onerous and the pay too often inadequate, but there are compensations, and many of the very best students—men of broad humanity with high intellectual gifts—choose family practice as their career. Their work is of the utmost value to the public and the profession, because it sets a standard for the branch of medicine in which the generality of students sooner or later become absorbed.

General practice is usually entered upon in one of three ways. The newcomer may take a house and wait for work to come to him, he may purchase the goodwill of a practice rendered vacant by retirement or death, or he may become a partner in an established firm. The first is more risky than the second, and the second than the third. A well managed partnership of three or more has this advantage over single-handed practice, that it allows each partner leisure for recreation and for keeping up with the progress

<sup>1</sup> *Handbook for Recently Qualified Medical Practitioners* 1926. British Medical Association, Tavistock Square, W.C.1. (3 6d net, 10 11s 3d 5d)

of medicine. Success in private practice demands a great deal of knowledge other than that gained at the medical schools, and hence a man is more likely to be accepted as a partner, or to do well on his own account if he has already some experience as an assistant or deputy. A considerable proportion of general practitioners, therefore, begin their work as assistants, and of these there are few who afterwards find cause to regret the time spent in learning the ropes under the eye of an experienced senior. As the conditions of general practice vary much in different parts of the country and even in the same district, it is usually best to undergo this post-graduate apprenticeship in circumstances resembling those to be encountered later.

An all-round knowledge of practical medicine, surgery, and obstetrics should, if possible, be supplemented by skill in some particular branch of work. Moreover what has been said about the advantage of having held one or more resident hospital posts applies with special force to general practice, for those who have been thus trained acquire a confidence and an experience not easily to be obtained elsewhere. The value of house appointments has been well put by Mr. I. B. Turner in an address to senior students and new graduates, which contained many hints and cautions about private practice and the work of the family physician.

The fundamental importance of the work done by the general practitioner is better appreciated now than in the past and it is more fully recognized that an efficient medical service for the community must be based upon the skill and devotion of the family medical attendant, working in close touch with the aims and methods of preventive medicine. Private practitioners to-day take a wider view of their duty towards the environment and the habits of their patients. The centre of gravity is shifting away from disease and towards health. The doctor of the future will come more and more to study early disturbances of function—the threshold of disease—and the maintenance of bodily and mental health.

While this is all to the good it cannot be denied that insidious inroads on private medical practice are continually being made under the auspices of the State and of voluntary bodies. This speaking generally, is not only against the interests of individual members of the medical profession, but, in the long run, against the public interest too. Furthermore, increasing contact with public authorities brings with it new and often irksome demands and the multiplication of official requirements and administrative checks has a tendency to cramp the doctor's independence of action. The national insurance system now more than fifteen years old, has already had a profound influence upon private medical practice. The Insurance Medical Service now comprises more than 14,000 doctors, some doing much work among insured persons, others little. In so far as they undertake these duties they are in effect part-time civil servants. But while the freedom and the individualism of the doctor have been restricted by the Insurance Acts and Regulations, there is a general belief (borne out by the findings of the recent Royal Commission) that the panel system has provided a better service than existed under the old 'club' arrangements, though it is by no means as complete or as effective as it might be made. Some of its worst faults have been removed through the efforts of the Insurance Acts Committee or the British Medical Association, which represents the interests of insurance practitioners in all negotiations with the Government.

One further remark should be made before leaving this subject. The strain of busy general practice is so heavy and often so continuous that only men and women of sound physique can expect to last the

course. Everything, therefore, should be done to promote bodily and mental fitness when work is slack and Mr. Turner's advice on the cultivation of outdoor sport and hobbies is very much to the point. Night duty, irregular meals, and long winter drives during epidemics will tax the strength of the strongest. One of the drawbacks of a single-handed practitioner's life is that, failing one arrangement with a neighbouring colleague, he is on duty twenty-four hours a day and seven days a week, and must be ready to answer a call as soon as it comes and however unfit for a fresh task he may feel.

#### CONSULTANTS AND SPECIALISTS

Where specialism begins and consulting practice ends would be hard to define, but the latter term may be said to cover in ordinary usage the work of the general medical consultant or 'pure physician' and that of the general surgical consultant or operating surgeon. Most general consultants, whether medical or surgical, are specialists in some branch of their practice and most if not all, specialists are consultants in the sense that their work largely comes to them through the recommendation of other practitioners with whom they act (or should act) in a consultative capacity. In any case whoever holds him self out as one or the other or both must be assumed to have knowledge and skill above the ordinary.

To be a competent specialist, as Mr. Turner says a man should have a comprehensive knowledge both of medicine and surgery and if possible should practice some years before starting on his own line of work. Intensive study is required of those who aim at becoming consultants or specialists and they should look upon hospital posts, especially where there are students to be taught, as a vital part of their own higher education. They must recognize too, that for them, as for practitioners of all branches, success will depend in the long run, not only upon mental gifts, special experience, and capacity for hard work, but on the possession of those qualities which inspire confidence both in patients and in colleagues. In the practice of medicine personal tact and character are as important as scientific equipment. Moreover, since the consultant or the specialist can scarcely hope at first to pay his way by consulting work or by the exercise of his specialty he must either have the means to support himself for an uncertain period, or be prepared by teaching or in other ways, to make ends meet. If while in preparation for his life work he can undertake some piece of research bearing upon his clinical studies this is strongly to be recommended.

Additional degrees and diplomas are important factors in securing election to the visiting staff of a hospital, and a few generalizations about them may be made here. Beyond the qualifications such as Bachelor or Licentiate, which admit to the *Medical Register* most of the licensing bodies bestow higher titles such as Doctor, Master or Fellow, after further tests. A considerable number of those who have graduated M.B. including many general practitioners, proceed later to the doctorate and the possession of an M.D. degree is certainly advantageous to anyone in consulting medical practice. When applying for the post of physician to a hospital it is always useful and may be obligatory to hold also the Membership of one of the three Royal Colleges of Physicians according to the part of the British Isles in which the hospital is situated. So too, the Fellowship of one of the three Royal Colleges of Surgeons should be obtained by those seeking surgical appointments and the degree of Master of Surgery is an added distinction. There are also diplomas in a growing number of special branches of work—public health, tropical medicine, ophthalmology, laryngology, radiology, tuberculosis, and psychological medicine—which are superfluous for most practitioners, but useful or even indispensable for those who

and tend to devote themselves to one or other of these subjects. Information about the several diplomas open to qualified practitioners, and about higher degrees, will be found elsewhere in this issue.

#### FINANCIAL AND SOCIAL CONSIDERATIONS

It is no easier now than in the past to assess the attractions of medicine as a means of livelihood. On the financial aspect of our profession two or three remarks only need be made, and those of the nature of truisms. Medicine is not to be regarded as a path to fortune, and anyone who enters it with the sole idea of making money has mistaken his calling. The competent practitioner can always make a living, but the main reward of the medical life is the knowledge of good work well done. Whatever the branch of medical work chosen, there are few doctors who become what a business man would consider even moderately rich by the practice of their profession. In this centenary year of Lord Lister's birth some words he addressed to new graduates in 1878 may well be quoted. "If we had nothing" (he said) "but pecuniary rewards and worldly honours to look to, our profession would not be one to be desired. Put in its practice you will find it to be attended with peculiar privileges, second to none in intense interest and pure pleasures."

If medicine, from the financial point of view, offers to the majority little more than the means of livelihood, in its social and intellectual aspects the prospect is far brighter. The culture which once belonged to the physician alone has spread into all ranks of the profession. The great improvement in the education, general as well as technical, of the practitioner has added much to his influence with the public, and has been a large factor in raising his social status during the sixty-nine years that have passed since the General Medical Council was constituted under the first Medical Act. A family doctor of the kind that is well styled "the backbone of the profession" occupies an excellent position among his neighbours, and is the friend and confidant as well as the medical adviser of many of his patients. Many men go further, and take a leading part in the public life of their district. How much good work of this kind can be accomplished during a long and arduous professional career may be found at the close of an interesting article published in these columns eight months ago.<sup>1</sup>

#### PROFESSIONAL ORGANIZATION

The spirit of comradeship, which adds so much to the value and happiness of undergraduate medical study, is at least as great a boon to the qualified practitioner. It should be preserved, both for its own sake and because in these days no doctor, whatever his position or the nature of his work, can safely stand aside from his fellows. Individuals and isolated bodies of practitioners are always handicapped when they attempt to defend their own interests, unsupported by their fellows, against organized bodies, whether these are Government departments, local authorities, or bodies of workmen. While in ordinary circumstances the individual doctor is quite able to deal with the individual patient and the patient's friends, he cannot hope to engage successfully in single combat with outside organizations.

Medical men and women must, therefore, band themselves together for their common protection, and the first step after registration should be to become an active member of the British Medical Association. Besides having behind him the machinery and the influence of a world-wide professional body, a young practitioner will find in the meetings of his local Division, and in the Annual Meetings of the Association, held in large medical

centres, many opportunities of keeping up with the progress of medicine and of friendly intercourse with colleagues. One other thing that no graduate should fail to do is to join immediately one of the professional societies which for a small yearly sum undertake individual legal defence of their members.

The British Medical Association was founded in 1852 to promote the medical sciences and to maintain the honour and interests of the profession. A brief note on its constitution and activities will be found at page 437. The Association, with Branches throughout the British Empire and a membership of more than 33,000, is the only body that can act for the profession as a whole and speak in its name. The record of ninety-five years' work shows that professional organization, wisely governed, can combine service for its members with service for the public. Much remains to be done in each direction, and the rising generation of doctors must not merely consolidate the ground won, but press forward. Every medical man and woman should cultivate a wide interest in the welfare of our profession, and try to take some share in the various movements, scientific or social or political, with which the Association has identified itself.

### PROFESSIONAL STUDY AND EXAMINATION.

#### A NOTE ON THE REVISED SCHEME

IN the year 1922 the General Medical Council prescribed a readjustment of the medical curriculum, to come into force at the beginning of the following year. In this readjustment, among other things, increased emphasis was placed upon sufficient opportunity being afforded for the study, both theoretical and clinical, of those subjects which are now so essential in connexion with the treatment centres of a local authority, such as ophthalmology, venereal diseases, orthopaedics and mechanical therapeutics, infectious fevers, anaesthetics, ante-natal conditions, and infant welfare. In the article at page 386 on the functions and requirements of the General Medical Council there will be found an account of the resolutions and recommendations of the Council which have applied since the beginning of 1923. We summarize below the leading features of the revised scheme of professional study and examination, and indicate the importance attached by the Council to the pre-graduate aspects of medicine. It must be remembered that no qualifying examination based upon this readjusted curriculum can take place until next year. Time has now been given for the universities, schools, and examining bodies to adjust themselves to these requirements, and we understand that an inquiry by the General Medical Council as to how far this has been done is now completed. It is expected that the results of this inquiry will be made public either in November next or early next year.

#### The Revised Curriculum

The minimum age for registration as a medical student is now 17 years. Formally, the length of the medical curriculum is not added to, practically it is, by referring to preliminary study and examination the subjects of elementary physics and chemistry in their purely scientific aspects. In the applications to the professional courses—as in biophysics, biochemistry, and pharmacological chemistry, appropriate instruction is to continue throughout the curriculum, and is to be tested by examination, so that the student shall no longer be able to put behind him as past and done with the knowledge which he acquired as a preliminary. If he has had no facilities at a secondary school or otherwise for obtaining what is necessary for the preliminary examination in these subjects, then he can come for it to the university or college, but study there will not count for the medical curriculum. In biology comparatively few secondary schools are equipped for elementary tuition, but the Council has suggested an arrangement for utilizing the work of such schools as are qualified for the purpose. The examination will not be "pre-curriculum," but the instruction may be so, and a

<sup>1</sup> Arthur C. J. Wilson, *Fifty Years in a Moorland Practice*. *British Medical Journal*, January 21, 1927, p. 30.

licensing body can allow students who so desire to sit for the examination immediately after matriculation. Heretofore, however, the applications of biology to medicine, surgery and midwifery will continue to receive attention throughout the course.

Besides the resolutions of the General Medical Council in regard to professional education and examination printed elsewhere a series of additional resolutions was adopted in 1922, as follows:

(a) That throughout the whole period of study the attention of the student should be directed by his teachers to the importance of the preventive aspects of medicine;

(b) That each Licensing Body should make adequate arrangements for the effective correlation of the several subjects of study throughout its curriculum;

(c) That the teaching of anatomy and physiology should include as a regular part of the courses the demonstration on the living human body of structure and function;

(d) That the curriculum should be so arranged that a minimum period of three years shall in every case be available for study after the completion by the student of the Professional Examinations in Anatomy and Physiology held at the close of the second year;

(e) That the curriculum should be so framed as to afford sufficient opportunities for the study during the last three years of the course of Physics, Chemistry, Biology, Anatomy, and Physiology in their practical application to Medicine, Surgery and Midwifery and that the student's knowledge of these applications should be subject to test in the Final Examination;

(f) That before the student is admitted to his clinical appointments he should have received practical instruction in clinical methods and in the recognition and interpretation of physical signs;

(g) That instruction should be given, in the course of Forensic Medicine and Public Health or otherwise on the duties which devolve upon practitioners in their relation to the State and on the generally recognized rules of medical ethics. Attention should be called to all notices on these subjects issued by the General Medical Council.

The Council, it will be noted attaches great importance to the reservation of sufficient time for the later subjects of study, free from all worries about passing the examinations of the earlier parts. To that end it recommends what is practically a block system. A minimum of three years should be available, not merely after the courses of anatomy and physiology have been taken, but after the examinations in these subjects have been passed.

#### Examination Reform

Another notable feature is that in assessing marks in the several examinations account may be taken of "duly attested records of the work done by the candidate throughout his course of study" in the subject. This is an effort to meet the long felt difficulty that a man's mental agility, or the want of it counts far too much in the examination room. The difficulty is real, but the remedy is not easy and the Council has been wise in the cautious approach it makes towards a solution. Where as in the examinations for the various conjoint diplomas, a student will only by chance come before his own teacher as an examiner, absolute impartiality in the attested records will be necessary. On the other hand, at the universities, where the teacher is almost always one of the examiners, no personal like or dislike of a student must influence the report of the internal to the external examiner. The class records should, of course, be available, but the scheme will put a serious ethical obligation on all concerned and the Council will doubtless watch its operation with keen and critical interest.

#### Training in Preventive Medicine

The first of the resolutions quoted above should be borne in mind by every teacher throughout the whole curriculum, and not merely in the clinical subjects. All the earlier subjects—physics, chemistry, biology, physiology, anatomy, and of course, pathology, bacteriology and therapeutics—should afford opportunities from the very beginning for instilling into the mind of the student the necessity for his keeping constantly in view in all the advice and

treatment he may give throughout his professional life, the primary importance of promoting the general health of those who entrust themselves to his care, and of preventing trivial ailments from developing into definite disease.

## THE NUMBERS OF THE MEDICAL PROFESSION.

### A REVIEW OF FIFTY YEARS

SINCE the year 1876 the General Medical Council has kept an analytical record of the number of names entered in, added to or removed from the *Medical Register* in each twelve months. The *Medical Register* has been published annually since the Council was constituted under the first Medical Act of 1858, but before 1876 no such data as these were ascertained or preserved.

In order to gain a general view of the numerical strength of the medical profession during the past fifty years we have extracted from the tables and set down below in parallel columns the total number of names in the *Medical Register* on December 31st of each year and the numbers added annually by registration between 1877 and 1926.

Numerical State of the Medical Register					
Year	Names added in Year	Total No. on Dec 31	Year	Names added in Year	Total No. on Dec 31
1877	940	22 841	1902	1 275	37,232
1878	936	22 600	1903	1 233	37 878
1879	996	22 516	1904	1 168	38 492
1880	1 123	22 930	1805	1 2 0	39 060
1881	1 053	23 275	1906	1 197	39 529
1882	1 171	23 801	1907	1 221	39 827
1883	1 304	24 517	1908	1 157	40 257
1884	1 338	25 321	1909	1 143	39 818
1885	1 377	25 933	1910	1 062	40 483
1886	1 431	26 452	1911	1 042	40 913
1887	1 531	27 246	1912	1 157	41 339
1888	1 184	27 939	1913	1 163	41 940
1889	1 306	28 548	1914	1 433	42 378
1890	1 258	29 163	1915	1 526	43 225
1891	1 345	29 555	1916	1 202	43 481
1892	1 513	30 590	1917	1 134	43 819
1893	1 579	31 644	1918	1 077	43 926
1894	1 426	32 637	1919	1 322	44 510
1895	1 445	33 601	1920	1 457	44 761
1896	1 385	34 478	1921	1 760	45 463
1897	1 259	34 602	1922	1 493	46 476
1898	1 210	35 057	1923	2 192	48 140
1899	1 351	35 836	1924	2 796	50 035
1900	1 345	36 355	1925	2 570	51 738
1901	1 318	36 912	1926	2 120	52 614

The following table indicates the varying proportion of registered medical practitioners to population during the period under review. It gives the population of the British Isles at each decennial census since 1881, and the number of names on the *Medical Register* in the same year, also the corresponding totals in 1925 that for the general population being in estimate.

#### Proportion of Practitioners to Population

Year	Registered Practitioners	Population British Isles
1881	23,275	35,241,482
1891	29,565	38,104,975
1901	36,912	41,976,827
1911	40,913	45,370,530
1921	45,463	47,145,506
1925	51,738	48,025,090

These figures show a tendency towards an increase in the ratio of doctors to population. The number of registered practitioners at the end of 1921 was almost exactly double the number at the end of 1876, but the population of Great Britain and Ireland within that period only increased by about 50 per cent. During the year 1926 the new medical registrations numbered 2,120 and there was a net increase of 876 names. Owing to the large increases during recent years reflecting the excessive entries of students immediately after the war there is now more than one name in the *Medical Register* to every thousand of population. In the United States of America, according to an estimate by the *Journal of the American Medical Association* there is at the present time one medical practitioner to every 753 people. Next to the United States the British Isles appear to have the highest proportion of practitioners to population.

## THE GENERAL MEDICAL COUNCIL

THE General Medical Council was established by the Medical Act, 1858, in order "that persons requiring medical aid should be enabled to distinguish qualified from unqualified practitioners." It consists of eighteen members appointed by the Universities in the United Kingdom having medical faculties of nine members appointed by the Medical Corporations, such as the Royal Colleges of Physicians and Surgeons, of five members appointed by His Majesty in Council, and of six members directly elected in members of the profession as a whole—a total of thirty-eight. To these are added three dentists who are members of the Dental Board, and are appointed for dental business. Although the eighteen members appointed by the Universities and the five members appointed by His Majesty in Council may all be laymen, only one layman has so far been appointed and that was by the Privy Council in 1926.

The Council's offices are at 44, Hillman Street, Portland Place, London, W 1, and it has Branch Offices at 20, Queen Street, Edinburgh, and 35, Dawson Street, Dublin.

The Council exists for the protection of the public and not of the profession. Its principal duties are, first, to see that no person obtains a qualification without a proper course of study and examination, secondly, to keep the *Medical Register*, and thirdly, to publish the *British Pharmacopoeia*. It is the appearance of a name upon the *Medical Register*, and not the possession of a degree or diploma, that constitutes a person a duly or legally qualified practitioner of medicine.

The Council has no power to make rules in regard to the medical curriculum or examination, but it can pass resolutions and make recommendations relating thereto, and if any of these were ignored by the licensing bodies, it would be open to the Council to make representations to the Privy Council, which if it thought fit might order that the qualifications obtained from such bodies should not be registrable.

The name of any medical practitioner who has been convicted of felony or misdemeanour, or who is proved before the Council itself to have been guilty of "infamous conduct in a professional respect," may be erased from the *Medical Register*.

The Medical Acts prohibit attempts being made to impose restriction as to the theory of medicine or surgery, and, once a practitioner has been trained and tested in the knowledge essential for public safety, he may adopt any "theory" of medicine or surgery in which he honestly believes. The Medical Acts do not prohibit the practice of medicine by unregistered persons, but if they "wilfully and falsely" assume any title implying registration they are liable to prosecution. In this respect the Medical Acts differ from the Midwives and the Dentists Acts, which entirely preclude the practice of midwifery or dentistry by unregistered persons. Unregistered medical practitioners, however, are under certain disabilities, for they cannot recover charges for medical or surgical attendance, etc., in a court of law, they cannot hold an appointment as a medical officer in the Military or Naval Services, or on ships, they cannot give any valid certificate which is required by any Act from a medical practitioner—for example, certificate of death, and they cannot obtain dangerous drugs.

An account of the recommendations that the Council has drawn up in respect of the education of medical students here follows.

### REGISTRATION OF MEDICAL STUDENTS

The Council recommends that every intending student of medicine should be registered as such at one of its three offices, whose addresses are given overleaf.

Candidates must produce evidence (a) that they have attained the age of 17 years, (b) that they have passed an examination in general education which is accepted for matriculation or entrance to the Faculties of Arts or Pure Science in a university in the United Kingdom, (c) and in addition thereto that they have passed in examination in elementary chemistry and elementary physics conducted or recognized by one of the licensing bodies.

Application for registration should be addressed to the Registrar for the division of the United Kingdom in which the applicant is residing—England and Wales, or Scotland, or Ireland. It must be made on a special form, which can be obtained from one of the offices of the General Medical Council itself or from one of the various licensing bodies and medical schools.

The regulations with regard to registration apply equally to medical and dental students, with the exception that in the case of the latter pupils with a registered dental practitioner may be regarded as a commencement of professional study, and that applications for registration should be addressed to the London office only.

### PROFESSIONAL EDUCATION

The rule is that it is only from the date which appears against his name in the *Students Register* that the medical student's career officially begins, thereafter five years at least must pass before he can present himself for the final examination for any diploma which entitles its lawful possessor to registration as a qualified medical practitioner under the Medical Acts, but to meet the circumstances brought about by the dates at which sessions of the medical schools begin and end, the close of the fifth year may be reckoned as occurring at the expiration of fifty-seven months from the date of registration. In any case, the period of five years must be one of bona-fide study, and in every course the following subjects should be included:

- (i) Elements of General Biology, including an introduction to Embryology. This course if the Licensing Bodies permit, may be taken before registration and the examination may be passed immediately after registration.
- (ii) Chemistry, Physics, and Biology in their application to Medicine.
- (iii) Human Anatomy and Physiology including Histology, Elements of Embryology, Biochemistry, and Biophysics.
- (iv) Elementary Bacteriology, prior to regular clinical appointments.
- (v) Pathology, general, special, and clinical, and Morbid Anatomy.
- (vi) Pharmacology and Materia Medica, to be taken concurrently with clinical instruction.
- (vii) Forensic Medicine, Hygiene, and Public Health.
- (viii) Medicine including Applied Anatomy and Physiology, Clinical Pathology and Therapeutics, Children's Diseases, Acute Infectious Diseases, Tuberculosis, Mental Disorders, Skin Diseases and Vaccination.
- (ix) Surgery, including Applied Anatomy and Physiology and Clinical Pathology, Anaesthetics, Diseases of the Eye, Ear, Throat, Venereal Diseases and Orthopaedics.
- (x) Diseases of Women, including ante-natal hygiene.

The Council recommends that during the last three of the five academic years clinical subjects shall be studied.

The first two years must be passed at a university, or at a school of medicine recognized by any of the licensing bodies enumerated in the schedule to the Medical Act of 1858, and the remainder must be devoted to clinical work at any public hospital or dispensary at home or abroad which is recognized by a licensing body.

### SPECIAL CONSIDERATIONS

The requirements of the General Medical Council in respect of the education of those who desire to enter the medical profession have now been given in outline, but before leaving this part of the subject the steps which the aspirant should take may be rehearsed in their due order:

- (1) Pass an examination in arts,
- (2) Pass an examination conducted or recognized by a licensing body in elementary physics and elementary chemistry,
- (3) Enter himself at a university or at a medical school recognized by one of the licensing bodies,
- (4) Obtain registration as a medical student,
- (5) Study for a minimum of five years certain prescribed subjects,
- (6) Meanwhile pass sundry intermediate examinations, and at the end of the fifth year pass a "qualifying examination" which will entitle him to receive from a licensing body a legal authority to practise.

**The Minimum Period.**—It must be remembered that the period of five years is a minimum, more is often required even by the man of good abilities and reasonable industry, and some of the universities prescribe a longer period. Besides these qualities a student, to obtain a registrable qualification in the minimum period of five years, or fifty-seven months, must have a considerable amount of good luck, in other words, he must keep in good health throughout.

In speaking of the minimum period it is to be remembered also that that time is only sufficient to obtain a respectable qualification such as a Bachelorship of Medicine, a Surgery or the diploma of the Royal College. Those who wish to take a higher qualification—for instance the F.R.C.S. Eng.—must prolong their work for another year or more. So too must in some cases, those who desire to convert their Bachelorship into a Doctorate. This may entail further formal examination, but at some universities the M.D. is obtainable on presentation of a thesis when the Bachelor has attained a certain age and has practised for a certain number of years. However, the student's career proper may be considered perhaps to have ended when he obtains his first registrable qualification for while preparing him self for any further tests he even usually does hold some junior appointment which more or less covers his expense.

Follow-up memorandum has been drafted and

The requirement for the registration of medical and dental students is the same and every intending student should in his own interest register as soon as he commences his professional education.

The requirement of the preliminary examination is generally education being satisfied it is then necessary for the student to pass a further or Pre Registration Examination (theoretical and practical) in Elementary Chemistry and Elementary Physics which is conducted or recognized by one of the licensing bodies. *These subjects may be pre-taken by a university or by a corporation. These subjects may be pre-taken in addition to those included in the preliminary examination—for example chemistry taken as one of the foundation required subjects in the preliminary examination cannot also count as one of the subjects of the Pre Registration Examination. These subjects may be studied at a university or medical school.*

The two examinations (in general education and in physics and chemistry) having been passed and the student having attained the age of 17 years, he should apply to one of the universities or one of the medical schools for admission to its course of medical study. When medical study has been begun, he should apply to the Dean of the school or to the Registrar of one of the branches of the General Medical Council for a form of application for registration. A student should have it completed and sent in to one of the Branch Councils as soon as possible. There is no fee for this registration. The medical curriculum will extend for at least five years, and the dental curriculum for at least four years from the date of registration as a student.

A dental student may continue his curriculum if he so desires as a pupil in dental mechanics of a registered dental practitioner but study at a dental school is to be preferred. If however he is apprenticed to a dental practitioner I will have to devote twice as much time to instruction in dental mechanics as he would if he had taken the subjects in a school as will have been the case in lengthening the curriculum. In any case a student can only obtain a certification of twelve months out of the four year curriculum.

#### PROFESSIONAL EXAMINATION

##### The Council's Recommendations

The following recommendations of the General Medical Council in regard to professional examinations for medical and surgical qualifications were adopted in May, 1922

1 In order to secure due continuity and sequence in medical study, two or more Professional Examinations in the earlier subjects should be held antecedently to the Final Examination in Medicine, Surgery, and Midwifery

2 Three years at least should intervene between the date of passing the Professional Examination in Anatomy and Physiology and that of admission to the Final Examination in Medicine, Surgery, and Midwifery

3 A candidate remitted in any subject of a Professional Examination should, before he is readmitted to examination therein, be required to produce satisfactory evidence that he has, during the interval of remission, pursued the study of the subject in which he was rejected. Candidates who obtain less than 30 per cent of the marks in any subject should be remitted for a longer period than three months

4 In all the Professional Examinations sufficient time should be assigned to practical work, in order to test the thoroughness of the candidate's knowledge and to encourage practical methods of study

5 Candidates in all their examination work should be carefully supervised

6 Two examiners should always participate in the oral examination of a candidate, except in subordinate parts of practical examinations

7 In all written examinations the questions in each subject should be submitted for the approval of all the examiners in that subject

8 In all written examinations an average of at least half an hour should be allowed for a candidate to answer each question

9 It is desirable that examiners, and in particular those for the Final Examination in Medicine, Surgery, and Midwifery, should be appointed or re-elected for at least three consecutive years

10 Whatever may be the system of marking, the percentage for a pass in each subject should not be less than 50

11 In the regulations for the several examinations it should be provided that examiners, in assessing marks, be empowered to take into account the duly attested records of the work done by the candidate throughout his course of study in the subject of the examination

12 The Final Examination in Medicine, Surgery, and Midwifery, with the exception of the Clinical and Practical Examination in Midwifery and Gynaecology, must not be passed before the close of the fifth academic year of medical study

13 The three portions of the Final Examination in Medicine, Surgery, and Midwifery should not be further subdivided into sections which may be entered for or passed separately

14 Compensation in respect of marks is between the three different portions of the Final or Qualifying Examination—namely, Medicine, Surgery, and Midwifery—is contrary to the intention of the Medical Act (1886)

15 The Final Examination should include clinical and practical examinations in Midwifery and Gynaecology

16 The clinical examination in Medicine, Surgery, and Midwifery should be held in properly equipped hospitals or examination halls well provided with suitable patients

17 In the examinations in clinical medicine at least one hour and in clinical surgery at least half an hour, should be allowed to the candidate for the examination of, and report on, his principal case

18 In Medicine, in Surgery, and in Midwifery, no candidate should be allowed to pass who fails to obtain 50 per cent of the aggregate marks assigned to the whole examination, or who fails to obtain 50 per cent of the marks assigned to the clinical examination, or who fails to obtain 40 per cent of the aggregate of the marks assigned to the written and oral examination. In Midwifery, where a clinical examination is not held, the duly attested records of the work done by the candidate in clinical midwifery must be presented to the examiners for assessment in the Final Examination, and no candidate should be allowed to pass who fails to obtain 50 per cent of the aggregate marks assigned to Clinical and Practical Midwifery and Gynaecology

19 The Final Examination should include the examination of secretions, the testing of urine, clinical microscopy, and prescription writing, and there should always be an oral examination in Medicine, Surgery, and Midwifery, which should include an examination on pathological specimens

20 At the Final Examination each candidate should be submitted to a practical and oral examination in Pathology (macroscopic and microscopic), unless this has been included in a Professional Examination preceding the Final Examination

21 Whatever be the method of entry for the Final Examination all candidates should be required to complete the three portions of the Final Examination within a period of nineteen months

This section of the Educational Number would be incomplete without brief mention of the memorandum, lately drawn up by the Registrar of the General Medical Council, on the procedure to be followed by those who desire to enter the profession of medicine to which reference is made in the introductory article at page 381. This pamphlet (price 1s post free) sets out in plain language the information for which the Registrar is often asked by prospective medical students or their guardians

## The English Universities.

THREE are eleven universities in England and Wales, and some account of each of them follows. They all have now fully developed medical faculties. Until recently the only exception was the University of Wales, whose constituent colleges are those of Aberystwyth, Bangor, Cardiff, and Swansea. This university grants degrees, and has laid down a six years' curriculum for candidates for the M.B. and B.Ch. degrees, and it now provides, at the Welsh National School of Medicine at Cardiff (see page 395), "the subjects of the medical curriculum"

## UNIVERSITY OF OXFORD

The professional degrees conferred by the university are those of Bachelor of Medicine (B.M.), Bachelor of Surgery (B.Ch.), Doctor of Medicine (D.M.), and Master of Surgery (M.Ch.). It also grants a Diploma in Public Health and a Diploma in Ophthalmology. On receiving the B.M. the candidate is entitled to registration by the General Medical Council. In favourable circumstances this degree and the B.Ch. may be obtained in six or seven years from matriculation. Before receiving either, the candidate must have taken a degree in arts (B.A.), for which three years' residence within the university is necessary. This, however, does not necessarily mean disform of professional study for that period for the subjects chosen for the arts course may be the same as those in which examinations would in any case have to be passed for the medical degree.

In accordance with a statute which came into force on October 7th, 1920, women may be matriculated and admitted to degrees in the university. The statute is retrospective under certain conditions. Before matriculation a woman must have been admitted as a member of one of the five societies of women students (Lady Margaret Hall, Somerville College, St. Hugh's College, St. Hilda's Hall, or the Society of Oxford Home Students). Women members of the university are admitted to all degrees except the divinity under the same conditions as those laid down for men in regard to examinations, courses of study, and fees and under corresponding conditions as to residence at the university. Among the university diplomas open to women are those in anthropology, ophthalmology and public health.

There are numerous avenues to the B.A. degree, but that which constitutes the normal course for medical students is the following. By passing Responsions (or one of the examinations which are accepted as equivalent) the Scripture examination, so one of the preliminary examinations in the Natural Science School, in the first public examination, and one of the final honour examinations in the Final Honour School of Natural Science—Physiology being that usually taken.

Responsions and the preliminary examinations in Natural Science may be passed before a candidate is a member of the university. A final honour school may be taken at the end of the third or fourth academical year—that is, within nine or twelve terms respectively. The preliminary examinations of the Natural Science School may be taken as soon as Responsions has been passed or exemption obtained.

## PROFESSIONAL DEGREES

To obtain the B.M. or B.Ch. degrees the candidate must first pass in four of the subjects of the Preliminary Examination of the Natural Science School—namely physics, chemistry, zoology, and botany.

He then has two further examinations to pass—the First B.M. and the Second B.M. The first takes place twice a year, the first on the Thursday, the second on the Wednesday, of the eighth week of Michaelmas and Trinity terms. Every candidate at the First B.M. is examined in human anatomy in physiology, and in organic chemistry, but is excused from physiology if he has obtained a first or second class in the Honour School of Physiology, and from organic chemistry if he has satisfied the examiners in Part I of the Honour School of Chemistry. Once he has passed this examination he can, on production of certain certificates, be examined as soon as he pierces in pathology, forensic medicine and hygiene, materia medica and pharmacology (subjects of the second examination), but cannot present himself for the remaining subjects—medicine, surgery and midwifery—until the eighteenth term from the day of his matriculation unless he be already a registered medical practitioner, and not until a period of at least thirty-three months has elapsed from the date of his passing the first examination, and he must pass in all the three subjects at one and the same time.

<sup>1</sup> The first subject of the medical preliminary examinations are four of the subjects in the natural science preliminary and can be commenced directly after passing Responsions.

<sup>2</sup> Membership is constituted by matriculation and by becoming either a member of a College or a Hall or a non-collegiate student.

Before admission to the Second B.M. examination the student must produce certificates of instruction from a medical school recognized by the university of having acted as clinical clerk and dresser, each for six months, and as post-mortem clerk for three months of attendance in labours of instruction in infectious and mental disease and ophthalmology and of proficiency in vaccination and the administration of anaesthetics. He must also produce certificates of attendance in laboratory courses in pathology, bacteriology and pharmacology either in Oxford or in a recognized medical school.

## D.M. AND M.Ch. DEGREES

A Bachelor of Medicine who wishes to proceed to the D.M. must have entered his fourth term and must present a dissertation for approval by the appointed examiners on a subject previously approved by the Regius Professor of Medicine. If a candidate for the M.Ch. he must have entered his twenty-first term and must pass an examination, which is held in June.

## D.P.H. AND D.O.

Examinations for the Diploma in Public Health are held in Trinity and Michaelmas terms, that for the Diploma in Ophthalmology is held annually in March. For the Diploma in Ophthalmology attendance on a twelve months course of clinical ophthalmology in hospitals or institutions recognized for the purpose by the Board of the Faculty of Medicine and on a course of instruction in Oxford lasting two months is obligatory. Candidates must have their names on the Medical Register of the United Kingdom, unless being Bachelors or Doctors of Medicine of universities outside the United Kingdom, they have obtained special permission from the Board of the Faculty of Medicine.

## TEACHING

The several colleges provide their undergraduate members with tutors for all examinations up to the B.A. degree. In addition the university provides certain courses of instruction including lectures, demonstrations, and practical work which cover all the subjects of the Preliminary Examination and First B.M. and those of the Final Examination.

## SCHOLARSHIPS

Most colleges grant scholarships open to intending medical students of the maximum value of £100 a year, tenable for four years in natural science, chemistry, physics and biology. Exhibitions of varying value are also awarded in these subjects. At two colleges (University and Pembroke) there are medical entrance scholarships of £100 a year. Particulars can be obtained on application to the college tutors. Scholarships for women are also offered by the various women's colleges from the principals of whom details of the examinations may be obtained. A Radcliffe Travelling Fellowship of £300 a year, tenable for two years, is conferred annually; candidate must have taken the B.M. degree. A Scherstein Research Fellowship of £200 a year for two years is awarded biennially. The Fellow must engage in research in one of the Medical Departments of the University. A George Herbert Hunt Travelling Scholarship of about £100 is awarded biennially to enable a young medical graduate to spend three months abroad in medical study. A Philip Walker Scholarship in Pathology of £200 a year, tenable for two years, is awarded biennially for the encouragement of research in pathology, as also are the Rolles on Memorial Prize and the Padellie Prize (£250) for research in natural science (including pathology) and the three Theodore Williams Scholarships in Anatomy, Physiology and Pathology of the value of £50 each, tenable for two years. A Radcliffe Scholarship in Pharmacology of £50 for one year open to the University is awarded annually by the Master and Fellows of University College. A Burney Teo King College Hospital Scholarship of £80 is awarded annually.

## FEES

An annual fee of £1 10s. is paid to the university for the first four years being reduced to £1 when the B.A. has been taken. For the degree the fees are the B.A. £7 10s. the B.M. and B.Ch. £14, the D.M. £25, the M.Ch. £12. College fees, varying in amount, are paid for the first four years of membership and in taking degrees. Tuition fees vary from £21 to £30. The minimum annual cost of living during the three university terms may be regarded as not less than £40 or for women not less than £1-0.

For further information application may be made to Dr. F. W. Ainslie Walker, Dean of the School of Medicine, University of Oxford.

<sup>3</sup> For the certificates that will be required from candidates are applicable to the new Regulations of the General Medical Council, Examination Statute, Clarification Press, Oxford, 1925 edition.

## UNIVERSITY OF CAMBRIDGE

The professional degrees given by this university are those of Bachelor of Medicine (M.B.) and Bachelor of Surgery (B.Ch.), each of which entitles the possessor to admission to the *Register* by the General Medical Council, and the higher degrees of Doctor of Medicine and Master of Surgery. It also grants Diplomas in Tropical Medicine, in Public Health, in Hygiene, and in Medical Radiology and Electrology to medical practitioners, not necessarily graduates of the university. Information regarding these diplomas will be found in later sections under the headings Tropical Medicine, Public Health, and Radiology. A candidate for the M.B., B.Ch. degrees need not possess a degree in arts, it is sufficient if he has passed the Previous examination or some other examination accepted by the university as its equivalent. Most students, however, are advised to take the B.A. degree, preferably by obtaining honours in the Natural Science Tripos at the end of their third year. Under the new regulations the attainment of a sufficient standard in chemistry or in physiology in this Tripos will secure exemption from the corresponding tests in the First and Second M.B. examinations. Women students, members of Girton College or Newnham College, are now admitted to the M.B. examinations.

## PROFESSIONAL EXAMINATIONS

To obtain the M.B. degree the candidate must pass three examinations, those who are finally successful may receive the B.Ch. degree (which is a complete registrable qualification) without further examination.

*First M.B.*—This comprises (1) general and inorganic chemistry, (2) mechanics, (3) physics, (4) elementary biology. The parts may be taken together or separately. In either case the candidate before admission to examination must have satisfied the requirements in respect of the Previous examination and have paid the registration fee. Certain exemptions from the First M.B. Examination are allowed, the regulations may be obtained from the Registrar. The complete examination is held twice a year—in October and June, an additional examination, in Parts 2 and 4, is held in December.

*Second M.B.*—This examination comprises Part I, organic chemistry, Part II, human anatomy and physiology, Part III, elementary pharmacology, including pharmaceutical chemistry and the elements of general pathology. No student is admitted to the first part of the second examination until he has passed the first part of the First Examination. No student is admitted to the second part of the Second Examination until he has passed all parts of the first examination. No student shall be admitted to the third part of the Second Examination until he has passed the first and second parts of the Second Examination. The candidate must be signed up in all three subjects and have dissected for one academic year. The examinations for Part I and II are held in December and June, that for Part III in October and April.

*Third M.B.*—This is divided into two parts, to neither of which is the candidate admitted until he has passed the examinations previously mentioned. A candidate for the first part, which deals with the principles and practice of surgery (including surgical pathology) and midwifery and diseases peculiar to women, must have completed five years of medical study and be signed up in these subjects and have completed two years and a half of hospital practice. Before admission to the second part the candidate must have completed five years of medical study, and be duly signed up in all subjects and have completed three years of hospital practice. He must also possess certificates showing that he has fulfilled all the recommendations as well as the requirements of the General Medical Council. The examination is in the principles and practice of physic (including diseases of children, mental diseases and medical jurisprudence), pathology (including hygiene and preventive medicine) and pharmacology (including therapeutics and toxicology). The Third M.B. examinations are held twice a year—in June and December.

*Act for the M.B.*—Before receiving his M.B. degree a

candidate who has been successful at the final M.B. examinations has to write a thesis. This he reads in public on an assigned day, and is then questioned concerning it and other subjects of medicine by the Regius Professor of Physic. If approved at this test he is then certified as having "kept the Act" satisfactorily, and in due course receives his degree. Medical degrees may be taken in absence by those living abroad, the candidate sending to the Regius Professor of Physic a dissertation, which is laid before the Degree Committee.

## THE HIGHER DEGREES

The M.D. degree may be taken by a Bachelor of Medicine of three years' standing (and a Master of Arts of four years' standing who has completed the course required for M.B.) after writing a thesis approved by the M.D. Degree Committee, and keeping a further Act, at which he reads his thesis and is examined thereon. Previously to the Act being kept a topic taken from the general subject of his thesis (whether it be physiology, pathology, pharmacology, practice of medicine, State medicine, or the history of medicine) is submitted to the candidate, on which he is required to write an extempore essay.

The M.Ch. degree may be granted to a candidate who has qualified for the B.Ch. at least two years previously, he is then examined in pathology, surgery, surgical anatomy, and surgical operations. The tests are partly in writing, partly oral, and partly practical; they include the writing of an extempore essay.

**FEES**  
In addition to college fees, tuition fees, and the expense of living, the following examination fees are payable: First M.B. £5 5s., Second M.B. £6 6s., Third M.B. £10 10s. For schedules referring to the examinations, lists of schools recognized by the university, and other information, application should be made to the University Registry, Cambridge.

## UNIVERSITY OF LONDON

Under the regulations of the University of London the degrees obtainable in the Faculty of Medicine are those of Bachelor of Medicine and Surgery, Master of Surgery in four branches, and Doctor of Medicine in six different branches. The university has its own matriculation examination and this is of so peculiar a kind that candidates should obtain and carefully study the booklets relating to it. The matriculation examination is open to any person, of either sex, who has attained the age of 16. It is held in January, June, and September, and lasts four days: the first two take place both in London and in certain provincial centres, the September examination is held in London only.

In no circumstances is a degree granted to anyone in less than three years after the date at which he passed the Matriculation Examination or obtained registration in some other way, and, unless they are already registered medical practitioners of a certain age and standing, all medical students must pass not less than five and a half years of professional study subsequent to matriculation, of which the last three years must be spent at a school of advanced medical studies.

## PROFESSIONAL EXAMINATIONS

*M.B., B.S.*—There are three examinations, the last two being subdivided. They are held twice a year.

The First Examination (held in July and December) covers inorganic chemistry, general biology, and physic, there being two papers, a practical test, and a possible oral test in each subject. The names of successful candidates are placed in alphabetical order, with a note as to any subject in which a candidate has distinguished himself or herself.

The Second Examination is held in March and July. Part I cannot be passed within six months of the passing of the First Examination. It covers organic chemistry, the candidate's knowledge being tested as in the oral examination. It is a pass examination, but a mark of distinction may be won. Candidates for Part II must have passed the First Examination at least eighteen months

previously besides having completed Part I of the Second Examination on The subjects are anatomy, physiology, and pharmacology the tests being written, oral, and practical. Candidates who fail in one subject may sit for re-examination in that subject alone if the examiners think fit.

No candidate is admitted to the Third M.B. B.S. Examination within three academic years from the date of his completing the Second Examination. The subjects are medicine (including mental diseases), pathology, forensic medicine and hygiene, surgery, and obstetrics and gynaecology. They may be divided into two groups, one comprising medicine, pathology, forensic medicine, and hygiene, and the other surgery and obstetrics and gynaecology. Either group may be taken first at the option of the candidate or the groups may be taken together. Only candidates who show a competent knowledge of all the subjects comprising a group are passed. There is no separate examination held for honours, but the names of successful candidates are divided into an honours list and a pass list and a university medal may be awarded the candidate who has most distinguished himself in the whole examination.

#### THE HIGHER DEGREES

**M.D.**—An examination for the M.D. is held twice yearly—in December and July. Every candidate must have passed the examination for the M.B. B.S. unless he became M.B. before May, 1904. He may present himself for examination in any one of the following branches: (1) medicine, (2) pathology, (3) mental diseases and psychology, (4) midwifery and diseases of women, (5) State medicine, (6) tropical medicine, and if he wishes, may pass also in another branch at a subsequent examination.

The period that must elapse between acquiring the M.B. and sitting for the M.D. in any branch varies between one and two years, according to the nature of the candidate's previous work and in all cases evidence must be afforded of special study of the subject chosen. Both written and practical examinations must be passed though exemptions can be obtained from the former in exceptional circumstances. In each branch the scheme of examination is the same: two papers on its special subject, a paper on an allied subject—for example medicine in the case of branch (4) pathology in branch (2)—an essay on one of two suggested topics connected with the special subject and a clinical or other practical test. In any branch of the M.D. Examination a gold medal of the value of £20 may be awarded.

**M.S.**—The regulations with regard to the Mastership in Surgery are of a corresponding kind but there are four branches in which it may be obtained—General Surgery, Dental Surgery, Ophthalmology and Laryngology, Otolaryngology and Rhinology.

#### FEES.

For Matriculation 2l guineas for each entry. For Examination 5 guineas for each entry to the whole examination. For re-examination in one subject the fee is 2 guineas. Second Examination Part I 3 guineas for the first and each subsequent entry. Second Examination Part II 9 guineas for each entry to the whole examination. For re-examination in one subject the fee is 4 guineas. M.B. B.S. Examination 12 guineas for each entry to the whole examination and 6 guineas for examination or re-examination in either group. M.D. and M.S. Examinations 20 guineas and 10 guineas on re-examination.

Inquiries should be addressed to the Academic Registrar, the University of London, South Kensington, S.W. 7.

#### UNIVERSITY OF BIRMINGHAM

THIS university confers medical and surgical degrees—namely, M.B. Ch.B., M.D., and Ch.M.—and also diplomas and degrees in State medicine and dentistry. It has a plan too by which extending his study to six instead of five years the M.B. Ch.B. candidate may become a Bachelor in Science as well. Of the five years' curriculum, the first four must be spent as a rule, at the university itself, the fifth being passed at any approved school or schools. Occasionally, however, the Senate will reduce the period of enforced residence to three years and exempt from the First M.B. (Part I) those who have passed elsewhere an examination

considered to be its equivalent. A degree of Ph.D. is also conferred for research study in medicine under special regulations. Candidates must be graduates in medicine of a recognized university.

Students entering the Medical Faculty for the M.B. Ch.B. degrees must have passed—

(1) Either (a) the matriculation examination of the Joint Board of the Universities of Manchester, Liverpool, Leeds, Sheffield and Birmingham or (b) some other examination recognized as equivalent to the matriculation. Candidates for medical degrees are recommended to take Latin and a science subject—chemistry or physics—at the matriculation examination, although these subjects are no longer compulsory. The matriculation examination of the Joint Board is held in July and September. The regulations and the list of examinations accepted in lieu thereof will be sent on application to the Secretary to the Board, Joint Matriculation Board, 315 Oxford Road, Manchester.

(2) A recognized pre-medical examination in the subjects of chemistry and physics—for example the Higher School Certificate of the Joint Matriculation Board—or a candidate may attend courses for pre-medical year in the university, October to June, taking chemistry and physics, and biology (optional).

For and after the session 1929-30 the passing of an examination in elementary biology will be compulsory before a student reads for the M.B. Ch.B. Birmingham or for any medical or dental degree or diploma in which an examination has to be passed in this subject, can enter the Faculty of Medicine.

#### PROFESSIONAL EXAMINATIONS

The candidate for the M.B. Ch.B. degrees has five examinations to pass. In the Second and Final examinations the candidate must pass in all the prescribed subjects or undergo the whole examination again.

The First M.B. (Part I) deals with elementary biology, and physical and organic chemistry. The First M.B. (Part II) deals with anatomy and physiology, and the student must pass in both simultaneously. The Second M.B. deals with pathology and bacteriology, materia medica and pharmacy. The Third M.B. takes place at the end of the fourth year, the subjects being forensic medicine, toxicology, public health and pharmacology and therapeutics.

**Final M.B.**—This comprises medicine, surgery, midwifery and diseases of women, ophthalmology and mental diseases. The candidate, in addition to more ordinary certificates, must be prepared with a certificate of having acted as a post-mortem clerk for three months and received special instruction in anaesthetics and clinical instruction in diseases peculiar to women, asylum ward work, ophthalmology, children's diseases, venereal diseases, ear and throat and skin diseases, etc. In respect to ophthalmology he must show that he has learnt refraction work. He also has to present to the examiners at the time of his examination a short written commentary on a gynaecological subject or case investigated during the period of gynaecological clerkship and certificate, drawn up by himself regarding four actual cases of lunacy and notes on two others.

**M.D.**—An ordinary candidate for this degree must be a M.B. Ch.B. of not less than one year's standing. He presents an original thesis for approval and then passes a general examination in the principles and practice of medicine. From the latter the Board of Examiners may exempt a candidate whose thesis is of exceptional merit. The regulations respecting the Ch.M. are of the same general character. Subject to certain requirements as to special research or other post-graduate study, graduates of other universities may obtain the M.D. and Ch.M. in the same way as holders of the Birmingham M.B. Ch.B.

#### FEES

The fee for matriculation is £2 (payable to Joint Matriculation Board), £2 10s. for pre-medical examination (if taken in University) and £2 10s. for each of the first four professional examinations. M.B. Ch.B. degree fee £10. M.D. and Ch.M. examinations, £12 10s. each. For further particulars application should be made to the Dean of the Medical Faculty, University of Birmingham.

## UNIVERSITY OF BRISTOL

In the Faculty of Medicine the following degrees are conferred Bachelor of Medicine and Bachelor of Surgery (M B and Ch B), Doctor of Medicine (M D), Master of Surgery (Ch M), Bachelor of Dental Surgery (B D S), and Master of Dental Surgery (M D S). There are also the following diplomas diploma in public health (D P H), diploma in dental surgery (L D S), and diploma in veterinary State medicine. All candidates for degrees in medicine, surgery, and dentistry are required to reach matriculation standard in the School Certificate Examination, or to pass such examination as may be regarded as equivalent by the Senate. All courses, degrees, and diplomas are open to men and women alike.

**Conjoined Degrees of Bachelor of Medicine and Bachelor of Surgery**—Candidates must be not less than 21 years of age and have pursued the courses prescribed by university regulations during not less than five years after passing the first examination in chemistry and physics, of which three shall have been spent in the university, and two of these three subsequent to passing the second examination. All candidates for the degrees of M B, Ch B are required to satisfy the examiners in the several subjects of three examinations.

**The First Examination**—The subjects of examination are chemistry (inorganic), physics, and biology, the courses pursued being those for the time being approved for the intermediate part of the B Sc curriculum. This part of the curriculum shall extend over one year. (Candidates who have passed the Higher School Certificate approved by the Board of Education in these subjects will not be required to sit for the First Examination and will be regarded as having completed one year of study.)

**The Second Examination**—The subjects of examination are organic chemistry and elementary anatomy (Part I) and advanced anatomy and physiology (Part II). Parts I and II may be passed separately or together.

**The Final Examination**—The subjects of examination are internal medicine and pharmacy, pharmacology and therapeutics, general pathology, morbid anatomy, and bacteriology (Part I), special pathology, forensic medicine, toxicology, and public health, obstetrics (including diseases of women), surgery (systematic, clinical, practical, and operative, including ophthalmology and oto-rhino-laryngology), medicine (systematic, clinical, and practical, including mental diseases) (Part II). The subjects included in Part II may be taken in two groups—namely, Group I surgery and obstetrics, Group II medicine, public health, special pathology, forensic medicine, and toxicology. Candidates may pass Parts I and II together or separately, and the two groups of Part II may likewise be taken together or separately, but no student can obtain honours who elects to take the two groups of Part II separately. Forensic medicine and toxicology may be taken either with Part I or with Group II of Part II.

**Degree of Doctor of Medicine**—Candidates must be Bachelors of the university of not less than two years' standing as such, and may elect either (1) to pass an examination in general medicine, or (2) to pass an examination in State medicine, or (3) to present a dissertation. The candidate who elects to pass the examination in State medicine must hold a diploma in public health of some university or college, and the candidate who elects to present a dissertation may be examined in the subject thereof.

**Degree of Master of Surgery**—Candidates shall be Bachelors of not less than two years' standing as such, during which period they shall have attended the surgical practice of an institution approved for the purpose. They shall pass an examination in surgical anatomy, pathology, and bacteriology, and operative, clinical, and general surgery, and present to the university a dissertation on some subject of surgery. The degree may be taken also in general surgery, and a special subject—for example, oto-rhino-laryngology, ophthalmology, and gynaecology.

**Diploma in Public Health**—Candidates must be at least 23 years of age, be fully registered medical practitioners of not less than two years' standing as such, and have passed the examination prescribed by regulation. The examination is divided into two parts.

## UNIVERSITY OF DURHAM

To its own undergraduates, who may be of either sex, this university grants the degrees of Bachelor of Medicine and Bachelor of Surgery (M B, B S), and Doctor of Medicine (M D), Master of Surgery and Doctor of Surgery (M S and D Ch), Bachelor of Hygiene, Doctor of Hygiene, and Bachelor of Dental Surgery and Master of Dental Surgery (B D S and M D S), it also grants diplomas in public health, psychiatry, and dental surgery. The university accepts the Durham University School Certificate Examination (if the required subjects are passed with credit) for matriculation purposes, but also accepts the tests of a considerable number of other educational bodies as a full or partial equivalent. A list may be obtained on application. In addition to satisfying the matriculation requirements of the university, every student must (1) pass a pre-registration examination in physics and inorganic chemistry conducted or recognized by the university, and (2) be registered on the books of the General Medical Council. To become a graduate, however, at the university it is not necessary to pass the major portion of the five years' curriculum within its precincts. It is sufficient if, before he presents himself for his final examination, the candidate has passed at least one year in study at the University of Durham College of Medicine, Newcastle-upon-Tyne, including the practice of the Royal Victoria Infirmary in the same city. The earlier examinations may be passed while the student works elsewhere.

## PROFESSIONAL EXAMINATIONS

There are four professional examinations for the M B, B S degrees. The First, Second, and Third Examinations are held in March, June, and December, and the Final Examination in June and December. The first deals with biology and organic chemistry, the second with anatomy and physiology, the third with pathology, bacteriology, materia medica, pharmacology, general principles of therapeutics, and pharmacy, medical jurisprudence, and public health. At the Final M B, B S the candidate is examined in medicine, clinical medicine and therapeutics, surgery and clinical surgery, midwifery and diseases of women and children, clinical and practical midwifery and gynaecology, and clinically in psychological medicine, diseases of the throat, nose, and ear, diseases of the skin, diseases of the eye, and diseases of children.

**M D**—A Bachelor of Medicine who wishes to proceed to this higher degree must be of at least two years' standing, and must comply with the regulations printed in the Calendar of the College of Medicine. If the candidate is not an M B of the university, he must be a practitioner of fifteen years' standing, 40 years of age, and submit to special tests. (See under Degrees for Practitioners, p. 416).

**M S**—Candidates for this degree must have been engaged in practice for at least two years subsequent to becoming M B, B S Durham. They are submitted to an examination which covers the whole range of surgical knowledge.

**D Ch**—The university grants also the degree of Doctor of Surgery. Candidates for this degree must be registered medical practitioners, not less than 24 years of age. They must devote three years, subsequent to obtaining a registrable qualification, to the study of surgery and medical subjects, one at least of the three years must be spent in the university. The candidate must submit to the professor of surgery the course of study he proposes to follow, and this course must be approved by the Board of the Faculty of Medicine.

One year must be devoted mainly to work in the departments of anatomy, physiology, pathology, and bacteriology, and the candidate must submit evidence of having so worked. Not less than six months of another year must be spent as a resident surgeon in a recognized teaching hospital, and the rest of the year in the study of surgery in a recognized medical centre. Not less than six months of one of the three years must be spent in surgical study abroad.

**Degree of Bachelor of Hygiene and the D P H**  
No candidate is admitted to the final examination for the degree of B Hy unless he is a Bachelor of Medicine and Surgery of not less than two years' standing, of a recognized university.

No candidate is admitted to the final examination for the DPH unless he is a registered medical practitioner or not less than two years' standing.

The course of study for the B.H. and DPH extend over a period of not less than twelve calendar months subsequent to the attainment of a preliminary qualification. Candidates for the B.H. must attend the course at the University of Durham or at any medical school or institution which is recognized by the university.

The examination for the diploma or degree consists of Part I and Part II each of which extend over not less than two days, and is conducted by examiners specially qualified. A candidate must pass in all the subjects of Part I before being admitted to examination for Part II. In Part I and also in Part II, a candidate must pass in all the specified subjects at one time.

The examination for Part I is practical, written and oral and includes the following subjects: bacteriology and parasitology (including medical entomology), chemistry and physics and meteorology and climatology in relation to public health. Candidates are not admitted to examination for Part I until after they have completed the prescribed courses of instruction in the subjects thereof.

The examination for Part II includes the following subjects: hygiene and sanitation (including sanitary construction), epidemiology and infectious diseases, sanitary law and vital statistics, public health administration. The examination is written and oral and includes practical examinations in infectious diseases, food inspection, inspection of premises—dwellings, factories, work-houses, schools, etc. Candidates are not admitted to examination for Part II until after they have completed the prescribed courses of instruction in the subjects thereof.

#### Doctor of Hygiene

Candidates for the degree of Doctor of Hygiene must be Bachelors of Hygiene of two years' standing and are required to satisfy the examiners that they have conducted original research in the subject of public health.

#### Diploma in Psychiatry

Candidates must be registered medical practitioners and unless qualified before January 1st 1911 must have attended subsequent to passing their qualifying examination course of instruction in (a) anatomy, (b) physiology, (c) pathology, (d) bacteriology, (e) psychology and experimental psychology, (f) clinical neurology, (g) psychiatry, (h) clinical psychiatry. The examination consists of two parts, namely: (1) anatomy, physiology, pathology and bacteriology, (2) psychology and experimental psychology, neurology, and psychiatry (systematic and clinical) and candidates may present themselves for the whole examination or for either part separately.

#### Licence and Degrees in Dental Surgery

**L.D.S.**—Every dental student must at the commencement of his studenthip be registered in the manner and under the conditions prescribed for medical students.

The First Examination consists of three parts which may be passed separately. Part I organic chemistry, Part 2 biology, Part 3 theoretical dental mechanics, dental metallurgy (theoretical and practical). Second Examination Anatomy, physiology (including biochemistry and histology), dental anatomy and dental histology. Third Examination Pathology and bacteriology, practical dental mechanics, dental materia medica and therapeutics. Final Examination Medicine, surgery, dental surgery and pathology, orthodontics, operative dental surgery and dental prosthetics and anaesthetics.

A candidate before presenting himself for examination is required to furnish certificates of instruction in the required subjects attended after registration as a dental student at recognized colleges or medical schools.

**Degree of Bachelor of Dental Surgery**—1—Students taking their complete course of instruction in the university must pass the same matriculation tests as medical students and the same pre-registration examination in inorganic chemistry and physics. After registration students must spend five years in the university. They must attend the practice of the Newcastle-upon-Tyne Dental Hospital for not less than two and a half years, six months of this time must be devoted to the study of the higher branches of dental science. There are four examinations. The subjects of the examinations are as follows: *First* Biology, organic chemistry and dental mechanics and metallurgy. *Second* Anatomy, physiology, dental anatomy and histology. *Third* Pathology and bacteriology, dental materia medica and therapeutics, and practical and dental mechanics. *Final* Medicine, surgery, dental surgery and pathology, orthodontics and operative dental surgery. In this subject knowledge of a much higher standard and more advanced practical work are required than for the Licence in Dental Surgery.

2—Candidates possessing a Licence in Dental Surgery of a British university must study for at least one year in the university. During such year they must (a) attend a course of instruction in pathology and bacteriology and (b) spend at least six months in the Newcastle-upon-Tyne Dental Hospital in the study and practice of the higher branches of dental science. They must also pass the third and final examination for the degree of Bachelor of Dental Surgery.

**Degree of Master of Dental Surgery**—Every candidate for this degree must be a Bachelor of Dental Surgery of the university of not less than two years' standing and present a essay embodying original work and research in some subject connected with dentistry. He must also perform to the satisfaction of the

examiners a piece of special dental work demanding a high degree of skill and experience.

The examinations are held concurrently with the medical examinations.

The practical examination in dentistry are conducted at the Newcastle-upon-Tyne Dental Hospital.

#### FEES

The following fees are payable: Matriculation £2. Examination—First Second and Third M.B. B.S. each £5. Final M.B. B.S. £15. M.D. and M.S. each £5. B.H. D.H. and D.P. each £10. 10s. and D.H. and D.Ch. each £20. First Second and Third L.D.S. each £5. 10s. and Final L.D.S. £5. First Second and Third B.D.S. each £5. Final B.D.S. £8. and M.D.S. £5. For degrees and diplomas: M.B. B.S. B.H. and B.D.S. each £8. 6s. plus the sum of 10s. if it is the initial degree taken in the university. M.S. and M.D.S. each £8. 6s. M.D. D.Ch. and D.H. each £10. D.H. D.I.S. and L.D.S. each £5.

Further information may be obtained from the Registrar, University of Durham College of Medicine, Newcastle-upon-Tyne.

#### UNIVERSITY OF LEEDS

The degrees granted in the Medical Faculty of this university are Bachelor of Medicine, Bachelor of Surgery (M.B. and Ch.B.) and Bachelor of Dental Surgery (B.Ch.D.), Doctor of Medicine (M.D.), Master of Surgery (Ch.M.) and Master of Dental Surgery (M.Ch.D.). It also gives diplomas in public health, in psychology, in dental surgery, and in nursing.

Candidates for the M.B. must have attended course of instruction approved by the university for not less than five years, two at least of such years having been passed in the university at least one year being subsequent to the date of passing the first examination. They must also have matriculated by satisfying the examiners in

- I. Full English Composition and English Literature or English Composition and History.
- II. Full Mathematics or Latin.
- III. Three other subjects not already taken under I and II above.
- IV. Chosen from the following list:

1. English Literature	9. Mathematics
2. History	10. Mechanics
3. Geography	11. Physics
	12. Chemistry
4. Greek	13. General Experimental Science
5. Latin	14. Natural History
6. French	15. Botany
7. German	
8. Some other language approved by the Board	

*Provided that* (a) candidates who take Mathematics and Latin must include one of the subjects 1-8. (b) candidates who take Latin under II above must include one of the subjects 9-15. In all cases Mathematics is a compulsory subject for admission to the Faculty of Medicine.

Exemption from the examination may be granted to applicants holding certificates of having passed examinations of a standard deemed by the Matriculation Board to be at least equal to the Board's examination.

#### PROFESSIONAL EXAMINATIONS

The examinations for the M.B., Ch.B. number three. The first deals with (1) Physics and Chemistry, (2) Biology. In each subject laboratory work is included but the two parts can be taken separately. For a further can the candidate present himself until after matriculation and a period of approved work in the respective subject.

**The Second Examination**—The Second Examination consists of Part I, Organic Chemistry, Part II, Materia Medica and Practical Pharmacology, Part III, Anatomy and Physiology, Part IV, Pharmacology. Candidates will be allowed to pass any parts separately.

**The Final Examination**—The Final Examination consists of Part I, Pathology and Bacteriology, Part II, Medicine, Surgery, Obstetric Gynaecology and Clinical Pathology, Part III, Forensic Medicine, Public Health and Therapeutics. Part I may be taken at the end of the second clinical year and must be passed before Parts II and III are taken. Parts II and III may be taken at the end of the third clinical year but not before the completion of the fifth year of medical study. It is taken separately Part II must be passed before Part III.

**M.D.**—A candidate for this degree must be a M.B., Ch.B. of the university or at least one year's standing. He presents a dissertation embodying the results of personal

of original research, and, if this is approved, he may be required to write a short extempore essay on some topic connected with medicine, and may be examined orally on the dissertation or other work submitted.

**Ch M**—The candidate for this degree must have been admitted to the M B, Ch B of the university not less than a year previously, and during that time must have held for at least six months a surgical appointment in a public institution affording full opportunity for the study of practical surgery. He must also have attended certain courses, including one on ophthalmology and one on bacteriology, he is then examined on the subject of surgery in all its branches.

#### FEES

The matriculation fee is £2, and on readmission £1 10s. For each of the other examinations £6 and £8 on readmission, Ch M £10 and same on readmission, M D £10. On conferment of the degree of Ch M £5 is payable, and £5 for the M D degree.

### UNIVERSITY OF LIVERPOOL

THIS university, besides granting degrees in medicine (M B and M D) and in surgery (Ch B, M Ch Orth, and Ch M), gives degrees in dental surgery (B D S and M D S), a degree in hygiene (M H), and degrees in veterinary science (B V Sc, M V Sc, and D V Sc). Diplomas are awarded in dental surgery (L D S), tropical medicine (D T M), tropical hygiene (D T H), public health (D P H), veterinary hygiene (D V H), and medical radiology and electiology (D M R E). The degree of Doctor of Philosophy (Ph D) may also be taken in the Faculty of Medicine.

#### MATRICULATION

The Matriculation Examination is governed by the Joint Matriculation Board, 315, Oxford Road, Manchester, which accepts, under certain conditions, the tests of several other bodies as its equivalent. Chemistry and physics are essential pre-registration subjects.

#### PROFESSIONAL EXAMINATIONS

Candidates for the M B, Ch B degrees have three examinations to pass, the first including (1) chemistry, (2) physics, (3) biology (zoology and botany).

**Second M B**—This test covers (a) (1) anatomy, (2) physiology, including physiological chemistry and histology, and (b) (3) elementary bacteriology, (4) clinical chemistry, (5) general pathology. Candidates may present themselves in (a) and (b) separately.

**Final M B**—The subjects of the Final Examination are—(a) (1) special pathology and morbid anatomy, (2) forensic medicine and toxicology, (3) public health, (4) pharmacology and general therapeutics, (b) (5) obstetrics and diseases of women, (6) surgery—systematic, clinical, operative, and practical—including ophthalmology, (7) medicine—systematic and clinical—including therapeutics, mental diseases, and diseases of children. Candidates may take Parts (a) and (b) separately, but Part (b) may not be taken until five years of study have been completed.

**M D and Ch M**—Candidates for these degrees must have received the M B and Ch B at least two years previously. Students holding equivalent degrees of other approved universities may become candidates for the M D degree after two years' study in the university or clinical school of the university. The M D candidate submits for approval

thesis covering original work in some branch of medicine or some science directly relative to medicine, together with, if desired, copies of published work, if the thesis is not judged to be of special merit an examination in either Medicine or some subject connected with the thesis is required. The M Ch candidate undergoes an examination. Other information concerning the diplomas of this university and its medical school will be found on page 409.

#### FELLOWSHIPS, SCHOLARSHIPS AND EXHIBITIONS

The university awards Fellowships annually to students of distinguished merit as follows:

(1) John Franklin Fellowships in Anatomy, two, each of the value of £120 tenable for two years. (2) Ethel Boyce Fellowship in Pharmacology, value £100 and tenable for one year, open to fully qualified medical students of either sex. (3) John W. Garrett Ingham Fellowship in Bacteriology, value £100 and tenable for one year. (4) J. B. ... Fellowship in Human Anatomy, value £100 and tenable for one year. (5) Holt Fellowships in Physiology and Pathology, two in number, value £150 each and tenable for one year. (6) Johnston Colonial Fellowship in Biochemistry, value £100 and tenable for one year. (7) Thelwall Thomas Fellowship in Surgical Pathology, value £150 and tenable for one year. (8) Lady Jones Fellowship in Orthopaedic Surgery, one value £200, offered every two years.

There are in addition, scholarships and exhibitions open to medical students.

### VICTORIA UNIVERSITY OF MANCHESTER

THIS university grants the four ordinary degrees in medicine and surgery—M B and Ch B and M D and Ch M, a degree and diploma in dental surgery, a diploma in public health, a certificate in factory and in school hygiene, a diploma in psychological medicine, and a diploma in bacteriology. Candidates for degrees must pass the special Matriculation Examination prescribed by the Faculty of Medicine (or some equivalent examination accepted in lieu thereof, see the prospectus of the Joint Matriculation Board), and study at the university itself for at least two years of the six years' curriculum, subsequent to the passing of the First M B Examination. The Matriculation Examination comprises (1) Latin, (2) mathematics, (3) the English language, its literature and history, (4) mechanics, (5) one subject at choice is approved by the Joint Board. It is held in July and September.

#### PROFESSIONAL EXAMINATIONS

**M B, Ch B**—There are four examinations for this degree. They must be passed in proper order, and before admission to them the candidate must be duly certified as having attended in the subjects involved. The First M B is divided into Part I, chemistry and physics, Part 2, biology—(a) botany, (b) zoology. The parts may be taken separately or together. At the Second M B the candidate is examined in anatomy (including histology) and physiology, at the third in pathology and pharmacology (including materia medica and practical pharmacy). The final Examination, under new regulations, is divided into two parts, which may be taken separately. Part I consists of (a) forensic medicine and toxicology, and (b) hygiene and preventive medicine. Part II consists of (a) medicine, including dermatology, diseases of children, and mental diseases, (b) surgery, surgical pathology, and diseases of the ear, nose, and throat, (c) obstetrics and gynaecology.

**M D**—A candidate for this degree must be a bachelor of medicine of at least one year's standing. He has a choice between presenting an original dissertation or undergoing a written (as well as practical and clinical) examination in medicine, and a written and practical examination in pathology, and one other subject selected by himself.

**Ch M**—A candidate must have held, since becoming Ch B, and for not less than twelve months, a post in a public institution affording opportunity for the study of the branch of surgery in which examination is desired. The examination in Branch I comprises the general field of surgery, Branch II, obstetrics and gynaecology, Branch III, ophthalmology, Branch IV, otology, laryngology, and rhinology.

**B Sc and M Sc**—The ordinary degree of B Sc in the Schools of Anatomy and Physiology may be obtained by students in medicine who in their third year of study for the degree of M B, Ch B complete the additional courses in these subjects prescribed for this degree. Candidates for the Honours degree of B Sc in Anatomy or Physiology who are students in medicine are required to attend courses in advanced anatomy and physiology for four terms after passing the Second Examination for the degrees of M B, Ch B. Graduates in science of this university, of not less than one year's standing from the date of their graduation as Bachelors, may proceed to the degree of M Sc by the presentation of an approved thesis on some subject coming within the scope of the Faculty of Science.

#### FEES

The following examination fees are payable. Matriculation, £2 on readmission £2. Each M B examination, £3 8s on readmission, £3 3s. M D, including the conferring of the degree, £15 15s. Ch M, £10 for the examination and £10 10s for conferring of degree. Application for further information should be addressed to the Dean of the Medical School.

## UNIVERSITY OF SHEFFIELD

The degree of this university (M.B., Ch.B., M.D. and Ch.M., B.D.S., and M.D.S.), the diploma in public health, and the diploma in licentiate in dental surgery, are open to candidates of either sex. Candidates for a degree must have matriculated in the university or have passed such other examination as may be recognized for this purpose, and have passed the further examination in chemistry and physics.

## PROFESSIONAL EXAMINATIONS

A candidate for the degrees of M.B., Ch.B. must produce certificates that he will have attained the age of 22 years by the day of graduation, that he has pursued the course of study required by the university regulations during not less than five years subsequent to the date of his matriculation or exemption from matriculation and the passing of the further examination in chemistry and physics three of such years at least having been passed in the university, one at least being subsequent to the passing of the First Examination. The following examinations must be passed in due order.

**First Examination.**—The subjects are chemistry, physics, and biology. Candidates who have passed the Intermediate Examination of the Faculty of Pure Science in any or all of the subjects of the First M.B. Examination will on payment of the fee for the latter examination be deemed to have passed it when they have passed in such subjects as they did not take for the Intermediate B.Sc. Examination. Candidates on presenting themselves for this examination are required to furnish certificates of having attended for not less than one year approved courses of instruction after matriculation and the passing of the further examination in physics and chemistry, in (i) chemistry, inorganic and organic; (ii) physics; (iii) biology.

**Second Examination.**—The subjects are anatomy and physiology. The candidate must have completed the second year of professional study must have passed the First Examination and must have attended (1) courses on anatomy including lectures and practical anatomy, during one year; (2) courses on physiology including lectures and practical physiology during one year.

**Third Examination.**—The subjects are pathology and pharmacology, anatomy and physiology. Candidates must have completed the last term of the fourth year of medical study and the requisite courses in these subjects, including post-mortem clerkship for three months.

**Final Examination.**—The subjects are Part I forensic medicine and public health; Part II medicine (including mental diseases and diseases of children); surgery; obstetrics (including gynaecology). Candidates for Part I must have completed Michaelmas term of the fifth year of study; candidates for Part II must have completed the fifth year of study.

**M.D.**—Candidates for the degree of Doctor of Medicine must have passed the examination for the degrees of M.B., Ch.B. at least one year previously must present a thesis embodying observations in some subject approved by the Professor of Medicine and must pass an examination in the principles and practice of medicine.

**Ch.M.**—Candidates for the degree of Master of Surgery must have passed the examination for the degrees of M.B., Ch.B. at least one year previously, and must, since taking the degrees of M.B., Ch.B., have held for not less than six months a surgical appointment in a public hospital or other public institution affording full opportunity for the study of practical surgery. The subjects of examination are systematic clinical and operative surgery, surgical anatomy, surgical pathology, and bacteriology.

Other information concerning this university will be found in the section devoted to Provincial Medical Schools.

## UNIVERSITY OF WALES

The Charter and statutes of the University of Wales provide *inter alia* for a Faculty of Medicine and for the granting of the following degrees: Bachelor in Medicine (M.B.), Bachelor in Surgery (B.Ch.), Master in Surgery (M.Ch.), and Doctor in Medicine (M.D.).

A candidate for the M.B., B.Ch. is required to pursue a

course of study of not less than six academic years subsequent to matriculation in the university, and of these years at least three must have been passed in one of the constituent colleges of the university. These are the University College of Wales, Aberystwyth, University College of North Wales, Bangor, University College of South Wales and Monmouthshire, Cardiff, and University College, Swansea. He must also hold an arts or science degree of the University of Wales or of some other university approved for this purpose. Certain of the courses of study pursued for a B.Sc. or a B.A. degree may be counted as courses required for the degrees in the Medical Faculty.

The courses for the M.B., B.Ch. are divided into two sections, of which the first includes the preliminary subjects—physics, chemistry, botany, zoology, and the ancillary subjects—organic chemistry, human anatomy and physiology. Study of the preliminary subjects and of organic chemistry must extend over at least one academic year; study of physiology and anatomy must extend over at least two academic years, the first section of the course must occupy not less than three years. The second section includes courses in pathology, bacteriology, pharmacology, hygiene and forensic medicine, medicine, surgery, and obstetrics and gynaecology, and cannot be commenced except in the case of pharmacology until the examinations relating to the preliminary and ancillary courses have been passed. Examinations in all the subjects are held in June of each year.

The university also offers courses of study in public health and in tuberculosis. Candidates for the Diploma in Public Health (D.P.H.) and for the Tuberculous Diseases Diploma (T.D.D.) must possess a medical qualification registrable for practice in Great Britain and Ireland and must have completed courses of study as prescribed by the regulations either at the Welsh National School of Medicine, Cardiff or at another institution approved by the university.

## WELSH NATIONAL SCHOOL OF MEDICINE

Students can complete the whole of their curriculum at the Welsh National School of Medicine, which is an integral part of the University College of South Wales and Monmouthshire, and qualify for the degrees of M.B., Ch.B. in the university.

Further information may be obtained from the Registrar, the University Registry, Cathays Park, Cardiff.

## English Medical Corporations.

There are in England three medical corporations which grant licences to practise—the Royal College of Physicians of London, the Royal College of Surgeons of England, and the Society of Apothecaries of London. The first two combine for certain purposes to form what is known as the Conjoint Board in England. Details concerning this body, its component Colleges and the third licensing body here follow.

## THE CONJOINT BOARD

This body—the Examining Board in England—deals with the qualifications of all candidates for the Licence of the Royal College of Physicians of London and for the Membership of the Royal College of Surgeons of England. It prescribes for them certain periods of study and recommends those who pass the required examinations for the Licence and for the diploma of Member respectively. The successful candidate is then entitled to register as L.P.C.P. (London) or M.R.C.S. (England). It performs the same task in connexion with diplomas in public health, tropical diseases, ophthalmic medicine and surgery, psychological medicine and laryngology and otology—jointly issued by the two Colleges in question. Under the new regulations which apply to all students who have not passed the required preliminary tests of general education before January 1st 1923, every candidate for the L.R.C.P. and M.P.C.S. must (1) complete five years of professional study after passing a recognized preliminary examination and a recognized pre-medical

examination in chemistry and physics, (2) comply with the regulations, which may be had from the Secretary, Examination Hall, Queen Square, London, W C 1, and (3) pass the two professional examinations of which particulars appear below. The old regulations for the Conjoint diploma, of which an account is given in the Educational Number for 1922, still apply to students who passed their preliminary examination in general education before January 1st, 1923.

#### NEW REGULATIONS FOR THE CONJOINT DIPLOMA

The following is an outline of the regulations applicable to candidates for the L R C P Lond and M R C S Eng who passed the required Preliminary Examination in general education on or after January 1st, 1923. The full regulations and synopses and forms of certificate may be obtained from the Secretary.

#### PRE MEDICAL EXAMINATION

Students are required to pass a Pre Medical Examination in Chemistry and Physics conducted by the Conjoint Examining Board before commencing the five years' curriculum of professional study or some other examination recognized by the Board—namely, the examination in Chemistry and Physics for the degree in Medicine of any university recognized by the Board, the Higher School Certificates of Oxford and Cambridge Universities and the Oxford and Cambridge Schools Examination Board, the Higher Certificates of London, Bristol, Durham Universities, the Joint Matriculation Board of the Northern Universities, the Central Welsh Board Higher Certificate, or the Pre Medical Examination in Chemistry and Physics conducted by any of the Qualifying Bodies whose Degrees or Diplomas are registrable on the Medical Register.

A candidate must enter for Chemistry and Physics together and he will not be allowed to pass in one without obtaining at the same time at least half the number of marks required to pass in the other subject. He will be admitted to the examination on producing evidence of having passed the required Preliminary Examination in General Education and of having received instruction during 180 hours in Chemistry and 120 hours in Physics to the satisfaction of his teachers. These courses may be commenced or attended before the required Preliminary Examination in General Education is passed.

The examination is partly written, partly oral and partly practical. A candidate rejected in one or both subjects of the examination will not be admitted to re-examination until after the lapse of a period of not less than three months, and he must produce evidence of further instruction in the subject or subjects of failure.

#### PROFESSIONAL EXAMINATIONS

There are two Professional Examinations, called the First and Final Examinations. The courses of study for the First Examination may be commenced before the Pre-Medical Examination in Chemistry and Physics or some equivalent examination has been passed provided three terms of study of anatomy and physiology are completed after passing such examination.

**First Professional Examination**—The subjects of this are Section I, (a) Anatomy including Histology and Embryology, (b) Physiology, including Biochemistry. Section II, Pharmacology, Practical Pharmacy, and Materia Medica. A candidate must have attended a School course of instruction in anatomy and physiology during five terms, during which he must have attended a body, courses of instruction in Physiology including General Biology, Biochemistry, and Bio-physics during five terms, courses of instruction in Pharmacology, Practical Pharmacy, and Materia Medica. A candidate may present himself for the two sections together or separately, but he must take parts (a) and (b) of Section I together until he has passed in one or both parts, but a candidate will not be allowed to pass in one part unless he obtains at the same time at least half the number of marks required to pass in the other part. Section II of the examination may be passed at any time before the candidate enters for the Final Professional Examination. A candidate who produces satisfactory evidence of having passed an examination in the subjects of Section I or of either part of Section I and of Section II in the examination for the degree in Medicine conducted at a university recognized by the Board will be exempted from further examination in such subject or subjects.

**Final Professional Examination**—The subjects of this are Section I Pathology (including Morbid Anatomy, Morbid Histology, and Clinical Pathology), and Bacteriology. Section II, Part I Medicine including Medical Anatomy, Forensic Medicine, and Public Health. Part II, Surgery, including Surgical Anatomy and the use of Surgical Appliances. Part III, Midwifery and Gynaecology. The examination is partly written, partly practical, partly clinical and partly oral. A candidate may take Sections I and II and the three parts of Section II of the Final Examination separately or may take the whole examination together. He will be required to produce the certificates prescribed by the regulations before being admitted to the respective parts of the examination. A candidate who produces evidence of having passed an examination for a degree in Medicine in the subjects of Pathology and Bacteriology at a university recognized by the Board is exempted from Section I.

#### FEES

The fee for the *Pre Medical Examination* is three guineas, for re-examination in Chemistry two guineas, and for re-examination in Physics one guinea. The fee for the *First Professional Examination*

is ten guineas, for re-examination after rejection in Section I six guineas, for re-examination after rejection in either part of Section I three guineas, for re-examination after rejection in Section II three guineas. The fee for admission to Section I of the *Final Professional Examination* is four guineas for admission to Section II, Part I, ten guineas. Part II ten guineas, Part III six guineas, and the re-examination fees are respectively three guineas, six guineas, and four guineas.

#### ROYAL COLLEGE OF PHYSICIANS OF LONDON

This College has three grades—its Licentiates, its Members, and its Fellows. The Licence is now only issued through the Conjoint Board. The Membership is only granted to those who have passed the final examinations for the Licence, or those who are registered practitioners and graduates of a recognized university, in any case they must be persons over 23 years of age. Candidates are examined in pathology and the practice of physic, partly in writing and partly *viva voce*, they are also examined in Latin, Greek, French, and German. The languages are not compulsory, but credit is given to those who show a knowledge of them. The fee for the Membership is £42, or in the case of a Licentiate £21. There is a fee of £8 8s, payable before entrance to the examination, which in the case of successful candidates is reckoned as part of the Membership fee. The body of Fellows is maintained by election from among the Members.

#### ROYAL COLLEGE OF SURGEONS OF ENGLAND

This College has two grades—Members and Fellows. The Members are admitted as stated in the section dealing with the Conjoint Board. The Fellowship is granted after examination to persons at least 25 years of age who have been engaged in professional studies for six years. There are two examinations for the Fellowship—the first in anatomy and physiology, which may be passed after the third winter session, the second, chiefly directed to surgery, which may be passed after six years of professional study. Candidates must pass the Final Examination of the Examining Board in England and be admitted Members of the College before admission to the Second Examination for the Fellowship, except in the case of graduates in medicine and surgery of not less than four years' standing of universities recognized by the College for the purpose, who are required to attend for one year the surgical practice of a general hospital recognized by the College after obtaining their degrees.

**Fees**—At first examination, £8 8s, for re-examination £5 5s. At second examination, £12 12s. Admission fee £10 10s for members, £31 10s for non members.

#### SOCIETY OF APOTHECARIES OF LONDON

This body confers a registrable diploma in medicine, surgery, and midwifery, now known as the L M S S A (Licentiate in Medicine and Surgery of the Society of Apothecaries), on those successful at the following examinations.

**Primary Examination**—This is divided into two parts, of which Part I includes chemistry, clinical physics, practical chemistry, and materia medica and pharmacy. Part II includes anatomy, physiology, and histology, and is not passed before the completion of twelve months' practical anatomy with demonstrations. Candidates will be examined in any or all the subjects of the primary examination on producing evidence that they have passed equivalent examinations before an examining body recognized by the Society. Candidates referred in anatomy will be required to produce evidence of further work in the dissecting room before being admitted to re-examination.

**Final Examination**—This is divided into three parts. Part I includes clinical surgery, the principles and practice of surgery, surgical pathology, operative manipulation, surgical anatomy, instruments and appliances. Part II includes clinical medicine (a) the principles and practice of medicine (including therapeutics, pharmacology, and prescriptions), pathology, and morbid histology, (b) forensic medicine, hygiene, theory and practice of vaccination, and

mental diseases. Part III includes midwifery, gynaecology, and diseases of newborn children, obstetric instruments and appliances.

The fee for the primary examination is £5 5s. for the final £15 15s. The regulations and synopsis relating to the several examinations and other information may be obtained from the Secretary, Court of Examiners, Apothecaries Hall, Blackfriars, E.C.4.

## The Scottish Universities.

There are in Scotland four universities each possessing a faculty of medicine, and having the right to confer degrees which admit the holder to the *Medical Register*. In essential points the regulations in their medical faculties for undergraduates are much alike, so that a general account can be given of all of them together.

The universities are those of Edinburgh, Glasgow, Aberdeen and St. Andrews. The provision each of the cities in which these universities are situated makes for the education of medical students will be found in the section on Medical Schools in Scotland, here it need merely be said that degrees in medicine from Scotland as a whole have always enjoyed a high repute.

The degrees granted in medicine and surgery to candidates of either sex are four in number—Bachelor of Medicine (M.B.), Bachelor of Surgery (Ch.B.), Doctor of Medicine (M.D.), Master of Surgery (Ch.M.). The two former are not obtainable one apart from the other. Besides these degrees a diploma in tropical medicine and hygiene is obtainable from the University of Edinburgh as also diplomas in preventive public health and radiology. As for public health registrable degrees in this subject are granted by the University of Glasgow while diplomas in public health may be obtained from the universities of St. Andrews and Aberdeen.

The conditions for admission of graduating students of medicine are the same as those in the faculties of Arts or Science (for degree in pure science).

As from January 1st 1923 prospective medical students are also required to pass a pre-registration examination in chemistry and physics.

### PROFESSIONAL EDUCATION.

The regulations comply in all respects with the requirements and recommendations of the General Medical Council, and in addition necessitate definite study for stated periods or disposes of children of the larynx, ear and nose of the skin of ophthalmology and of mental diseases. In respect of the various courses certificates must be obtained showing that the student has not only attended regularly but has duly performed the work of the class. Out of the necessary five years of medical study, not less than two must be spent at the university whose degrees the student hopes to obtain and the balance at any place officially recognized for such purpose. In each academic year there are two sessions—one lasting from the beginning of October to the middle of March and the other from the middle of April to the beginning of July.

### PROFESSIONAL EXAMINATIONS.

The distinctive feature of the Scottish curriculum is that though nominally there are only four examinations each of these may be, and habitually is split up by the student into sections. Hence a student may complete some stage of his career during the course of nearly every session. Thus by the end of the first winter session the student may pass in zoology and chemistry. At the end of the first summer session he can finish with botany and physics and with anatomy and physiology at the end of the second. Pathology and either a medical or a surgical subject at the end of the third year and so on until the final examination in midwifery, surgery and medicine and the corresponding clinical subjects, at the end of the fifth year of study. At each examination the candidate may pass "with distinction" and a record is kept of the merit displayed so that, when the time comes for the candidate to graduate, one who has done well throughout can be declared as

graduating with honours. A further point in the system is that the student's own teachers commonly take some part in his examination.

Of the four examinations, the first deals with physics, botany, zoology, and chemistry, the second with anatomy and physiology, the third with materia medica and pathology, the fourth with medicine and surgery (clinical and systematic), midwifery, clinical midwifery, and clinical gynaecology, and forensic medicine and public health. The first three examinations are held three times a year, the final twice a year.

Exemption from the first professional examination can be obtained by candidates who have passed in arts, science, or medical degree examination in its subjects at any recognized university. When a candidate presents himself for an examination in several of its parts, but is not successful in all of them, he is credited at the next examination with those subjects in which he has already been approved.

### THE HIGHER DEGREES.

It is open to those who are already M.B., Ch.B. to proceed either to the M.D. or the Ch.M. A candidate for the former must have been engaged for not less than one year in work in the medical wards of a hospital, or in scientific research in a recognized laboratory or in the Naval or Military Medical Services or have been at least two years in general practice and he must be 24 years of age. He has to write a thesis on any subject not exclusively surgical, and is examined in clinical medicine and in some one or other of its special departments. The regulations for candidates for the Ch.M. are of a corresponding character a period of surgical work in a hospital or elsewhere being substituted for medical work and the thesis being on a surgical rather than a medical subject. He is examined in surgical anatomy, clinical surgery, operative surgery, and in some of the special departments of surgery.

### FEES.

It is estimated that the class examination and other fees for the M.B., Ch.B. come altogether to about £225 the separate examination fees included in this calculation being as follows:

	£	s.	d.
First Professional	9	9	0
Second Professional	7	7	0
Third Professional	6	6	0
Final	11	11	0

Entry in any subject in which the candidate has failed entails a fresh payment of £11s. Candidates for the M.D. and Ch.M. pay £21 and on re-entry £5 5s.

More detailed information with regard to the University of Edinburgh can be obtained from the *Medical Programme*, price 6d which is published by Mr. Thun, 55 South Bridge, Edinburgh or on application to the Dean of the Faculty of Medicine. Similar information about Glasgow should be sought from the Assistant Clerk, Matriculation Office, Glasgow. With regard to Aberdeen application may be made to the Secretary of the Medical Faculty, Marischal College. In respect of St. Andrews information can be obtained either from the Secretary or the University or, alternatively, the Secretary of the United College, St. Andrews or the Secretary of University College, Dundee the latter being the two constituent colleges of the University of St. Andrews.

Finally it should be mentioned that in connexion with all the Scottish universities there are valuable bursaries and scholarships some information as to which will be found in the article on Medical Schools.

### THE CAMBIE TRUST.

The following is a summary of the regulations made by the Cambie Trust for the Universities of St. Andrews and for a scheme in the payment of class fees in the universities and extra-mural colleges of Scotland.

Applicants must be over 16 years of age, they must be of Scottish birth or extraction or have attended for two years after the age of 14 at a school or institution under inspection of the Scottish Education Department. Applicants so qualified who have been pupils of a school under the Scottish Education Department will be eligible for a remission in the payment of class fees if they have obtained the leaving certificate of the Department provided that it bears evidence of such preliminary education as is required by the universities for their graduating curricula or that it has

been supplemented by such passes either in the Scottish Universities or by other examination as will satisfy the above requirement of the universities. Where applicants have not been pupils of schools under the Scottish Education Department, or where other good ground for not having obtained the leaving certificate can be shown, the Executive Committee has power to accept instead what it deems equivalent evidence of attainments.

Applicants in the Faculties of Arts and Science must have had their course of study for each academic year approved by the University Adversary of Studies, and they must have passed the graduation examinations belonging to the previous stage of their curriculum before becoming eligible for assistance in the payment of fees of classes belonging to a further stage. Beneficiaries must submit to the Executive Committee at the end of each session particulars as to their attendance and work and distinctions gained, and any graduation examinations passed.

The annual allowance towards payment of class fees offered to beneficiaries by the Trust in the Faculty of Medicine is £19 for four years in all £76. Any unexpended part of a grant will be carried forward to the succeeding year. In combinations of Faculties the allowances available for beneficiaries are Arts and Medicine—two Arts grants of £8 and four Medicine grants of £19, in all £92. Science and Medicine—two Science grants of £17 and four Medicine grants of £19, in all £110.

Applicants, in writing for application forms, must name the university and faculty in which they intend to study, and state whether they have previously obtained the benefits of the Trust. Applications must be lodged not later than October 25th for the winter session, or May 10th for the summer session. Payments are made by means of fee coupons and fees already paid are not refunded.

## The Scottish Corporations.

THERE are three medical corporations in Scotland—the Royal College of Physicians of Edinburgh, the Royal College of Surgeons of Edinburgh, and the Royal Faculty of Physicians and Surgeons of Glasgow. Their licences can be separately obtained only by persons who are already in possession of a recognized qualification—in surgery in the case of the College of Physicians, and in medicine in the case of the College of Surgeons and the Faculty of Physicians and Surgeons of Glasgow. All others must submit to the examinations held by the Conjoint Board which the three corporations have combined to form. Details concerning this Board and its component colleges follow. The conditions on which their higher qualifications are granted will be found set forth separately in connexion with each corporation.

### THE CONJOINT BOARD IN SCOTLAND

THIS body has charge of all questions connected with candidates for the Conjoint Licences of the Royal College of Physicians of Edinburgh, the Royal College of Surgeons of Edinburgh, and the Royal Faculty of Physicians and Surgeons of Glasgow. Those finally approved by it are entitled to registration and to the titles denoting the Licences of the three bodies concerned—namely, L R C P Edin, L R C S Edin and L R F P S Glas. The Board requires all candidates to comply with the regulations of the General Medical Council. It has an Arts examination of its own, but is prepared to accept in its place any of the other educational tests approved by the General Medical Council. All candidates must obtain registration with the General Medical Council.

#### *Professional Curriculum for Candidates registered as Medical Students prior to January 1st, 1923*

Subsequent to registration is a medical student the candidate must pass not less than five years in medical study, each comprising a winter and a summer session. The Board does not insist that candidates shall pursue their study at any particular place, and is prepared to accept certificates of having attended the necessary courses from any recognized medical school.

Its examinations are four in number, each of them being held four times every year, and these will fall to be held twice in Edinburgh and twice in Glasgow during the next period it is open to candidates to present themselves for examination at either place. The first examination deals with physics, chemistry, and elementary biology, the second with anatomy and physiology, including histology, the

third with pathology and materia medica, including pharmacy, and the final with (1) medicine, including therapeutics, medical anatomy, and clinical medicine, (2) surgery, including surgical anatomy, clinical surgery, and diseases and injuries of the eyes, (3) midwifery and diseases of women and of newborn children, including clinical gynaecology and practical midwifery, and, if it has not been passed previously, (4) medical jurisprudence and hygiene. Candidates will also be examined on diseases of children, diseases of the ear and throat, insanity, vaccination, etc.

These examinations must be passed in due order, and before admission to any of them the candidate must supply certificates showing that he has completed the due periods of study of these subjects. He can present himself in any single subject of the first three examinations. As regards the final examination, a candidate can present himself in medical jurisprudence and hygiene at any time after completion of the third examination and of his study of these subjects, but in medicine, surgery, and midwifery he cannot present himself until the completion of five years' study, and he must take them all simultaneously. A candidate who takes up several subjects of an examination or the whole of the subjects at one time, but fails in some of them, is credited at the next examination with those subjects in which he has been approved.

All candidates for the Final Examination must complete the pass in the three portions (medicine, surgery, and midwifery) within a period of nineteen months.

Part or entire exemption from the first three examinations may be granted to those who have already passed before other bodies examinations deemed by the Board equivalent to its own, but all candidates for the Conjoint licence must sit for the Final Examination and at no examination can a candidate present himself within three months of his rejection by some other licensing body.

#### *Professional Curriculum for Candidates registered as Medical Students after January 1st, 1923*

The curriculum has been extended to meet the recommendations of the General Medical Council. Candidates, when applying for copies of regulations, should state date of medical registration.

#### FEES

It is estimated that the total cost of lectures and fees for the Conjoint licence is about £152. The separate examination fees are as follows: First, Second, and Third Professional, £5 each; Final £15. On re-entry for any of the first three examinations £3 and on re-entry for the Final, £5. If the re-entry is only in one or two subjects of the First, Second, or Third Examinations the fees are smaller.

Information concerning this Board should be sought either from Mr D. L. Fyvie, 49, Leamington Place, Edinburgh, or from Mr Walter Hurst, Faculty Hall, 242, St Vincent Street, Glasgow.

### ROYAL COLLEGE OF PHYSICIANS OF EDINBURGH

THIS College has three grades—Licentiate, Membership, and Fellowship—all of which are open to men and women. The regulations applying to candidates for the Licentiate have already been generally indicated. If desirous of receiving it apart from those of the other two corporations they must be holders of a surgical qualification recognized by the College, and must pass an examination corresponding to the medical part of the Final Examination of the Conjoint Board, and conditioned in the same way, and also an examination in materia medica. The fee for examination is 15 guineas, a special examination being obtainable on due cause being shown, and on payment of 5 guineas extra. Ordinary examination takes place monthly on the first Wednesday and Thursday, except in September and October. Candidates for the Membership must be either Licentiates of a British or Irish College of Physicians, or alternatively graduates of medicine of a university approved by the Council, and in either case not less than 24 years of age. Candidates are examined in medicine and therapeutics, also on one or more departments

of medicine specially professed and approved by the Council, in which a high standard of proficiency will be expected. The fee to be paid by a candidate for the Membership is £36 15s. The examination is held quarterly and application for admission to it must be made a month previous to its date. For the Fellowship the candidate must have been a Member of the College for at least three years and if accepted, pay fees including £25 stipend duty amounting altogether to £64 18s. Further details can be obtained on application to the Secretary of the College.

### ROYAL COLLEGE OF SURGEONS OF EDINBURGH

This College has two grades—its Licence and its Fellowship. Licentiates may be of either sex, and for the Fellowship women are eligible also.

#### Licence

As an original qualification the Licence is only granted after fulfilment of the regulations of the Conjoint Board but as an additional qualification it can be obtained by those already possessed of a registrable or equivalent qualification in medicine. In this case the candidate has to pass a written, oral, and clinical examination in surgery and surgical anatomy, and may be asked to operate on the dead body.

The fee is £15 15s. of which £10 10s. is returned to unsuccessful candidates. Or on the candidate being shown a special examination may be granted the fee being £20 of which £10 is returned to a candidate if he is not approved.

#### Fellowship

Candidates for the Fellowship must be not less than 25 years of age and have been in the practice or study of their profession subsequent to registration for at least two years and must hold either a surgical degree from a university recognized for that purpose by the College or a registrable diploma obtained as the result of an examination which includes surgery as well as medicine and midwifery. Candidates are examined in (a) the principles and practice of surgery including surgical anatomy, (b) clinical surgery, and (c) one optional subject which they may choose from among the following: surgical pathology and operative surgery, ophthalmology, laryngology, otology, and rhinology, gynaecology, obstetric surgery, anatomy, and dental surgery and pathology. The examination is written, oral, and clinical or practical. A candidate who desires to be examined must give one month's notice. His application for admission being supported by two Fellows of the College, one of whom must be resident in Edinburgh or in default by testimonials specially obtained for the purpose. Candidates are not allowed to appear more than three times at the examinations.

Licentiates of the College pay £35 and others £45. For further information application should be made to the Clerk of the College Mr D. L. Eadie, 49 Lauriston Place, Edinburgh.

### ROYAL FACULTY OF PHYSICIANS AND SURGEONS OF GLASGOW

This body possesses two classes—Licentiates and Fellows. The regulations applying to the former correspond with those respecting candidates for the Licence of the Royal College of Surgeons of Edinburgh. Candidates for the single Licence are examined in surgery (including clinical surgery and surgical anatomy). The fee is £15 15s. and examinations are held quarterly. Candidates for the Fellowship must be qualified medical men of not less than two years' standing and 24 years of age. Candidates approved at this examination are then eligible for election as Fellows. The Faculty can also elect four Fellows annually without previous submission to examination provided they "have highly distinguished themselves in medical science or practice." They must be of not less than ten years' standing and 40 years of age.

The fee for the Fellowship is £50. Further information can be obtained from Mr Walter Hurst, Faculty Hall, 242 St Vincent Street, Glasgow.

## Irish Universities and Corporations.

### MEDICAL REGISTRATION IN THE IRISH FREE STATE

THE Medical Practitioners Act 1927 (Irish Free State) provides for the establishment of a Medical Registration Council for the Irish Free State. The main functions of the Council will be (1) to keep a register of medical practitioners who may desire to practise permanently or temporarily in the Irish Free State, and (2) to exercise disciplinary power with regard to all medical practitioners who are on the register and engaged in practice in the Irish Free State. The first schedule of the Act contains the agreement between Great Britain, the Irish Free State, and Northern Ireland. This agreement provides for the nomination of a member of the General Medical Council formerly made for Ireland by His Majesty on the advice of the Privy Council to be made henceforth by His Majesty in Council on the recommendation of the Governor of Northern Ireland. The nominations of members of the General Medical Council by universities and medical corporations in Ireland and the election of a member of the General Medical Council by registered medical practitioners in Ireland will be in all respects the same as heretofore. The constitution of the General Medical Council and of the several Branch Councils as formerly existing under the Medical Acts and the powers of holding qualifying examinations and granting diplomas for the purpose of registration in the general Register formerly vested in certain universities and medical corporations in Ireland are not affected by the establishment of the Irish Free State or of Northern Ireland and for the purpose of the preparation and keeping of the general Register the General Medical Council and the Branch Council for Ireland shall have the same powers and jurisdictions under the Medical Acts as they exercised formerly. The agreement provides also that any person who is or shall be registered in the general Register shall be entitled on the payment of a prescribed fee to be registered in the Irish Free State Register but this fee will not be payable by any person who on the date of the establishment of the Irish Free State Medical Register, is registered on the general Register. Then follow provisions with regard to the erasure from the Register of the name of a person on account of misconduct.

### THE IRISH UNIVERSITIES

There are three universities in Ireland, each with a medical faculty. These are in the Irish Free State the University of Dublin (usually known as Trinity College, Dublin) and the National University of Ireland, and in Northern Ireland, the Queen's University of Belfast.

### UNIVERSITY OF DUBLIN TRINITY COLLEGE

This university grants two degrees in medicine (M.B. and M.D.), two in surgery (B.Ch. and M.Ch.), two in midwifery (B.A.O. and M.A.O.) and a post-graduate diploma in public health. It also grants post-graduate diplomas in gynaecology and obstetrics for which nine months' study is required and in psychological medicine, for which twelve months' study is required. The degrees are granted to those who having passed the Professional Examination, have also graduated in arts.

#### PROFESSIONAL EXAMINATIONS

A candidate for the Final Examination for the M.B., B.Ch. and B.A.O. degrees must be a matriculated student of at least five years' standing. The examinations which students must pass are the Preliminary Scientific, the Intermediate Medical, and the Final. Before admission to any of these examinations students must have completed the course of study in the subjects involved.

Preliminary Scientific—This covers (a) chemistry, (b) physics, (c) botany and zoology; the three divisions may be taken together or at different times.

**Intermediate Medical**—This is divided into two parts (a) anatomy, physiology, organic chemistry, and histology, (b) applied anatomy and applied physiology. The two parts may be taken separately or together.

**Final Examination**—Part I Hygiene and medical jurisprudence, pathology and bacteriology, materia medica and therapeutics. Part II (a) Midwifery and gynaecology, (b) medicine and mental diseases, (c) surgery in all branches including clinical ophthalmology. The three sections of Part II may be taken separately or together. In either case the full curriculum must have been completed and the Final Examination cannot be completed before the end of the fifth year.

**M D**—The candidate must have passed all the qualifying examinations in medicine, surgery, and midwifery, and have taken, or have been qualified to take, the degree of B A three years previously. He must send in a thesis for approval. Subsequently the Regius Professor of Physic and an assessor will discuss with him questions connected with the thesis, and may also examine him *viva voce* on other medical subjects of a more general nature.

**M Ch**—The candidate must be a B Ch of not less than three years' standing, and have been engaged in practice for two years.

**M I O**—The candidate must be a B A O of not less than two years' standing and must produce satisfactory evidence of having been engaged for two years in obstetric science. The examination is specially directed to obstetrics and practical gynaecology.

Further information regarding courses of instruction, etc., may be obtained from the Registrar of the School of Physic, Trinity College, Dublin.

### QUEEN'S UNIVERSITY, BELFAST

The degrees granted by the Medical Faculty of this university are as follows: Bachelor of Medicine (M B), Bachelor of Surgery (B Ch), Bachelor of Obstetrics (B A O), Doctor of Medicine (M D), Master of Surgery (M Ch), Master of Obstetrics (M A O). The university also confers a Diploma in Public Health. The first three degrees mentioned serve as a qualification for admission to the *Medical Register*, and are not granted separately. In addition to matriculating and passing his professional examinations, a candidate for these degrees must have passed three of the regulation five years as a student at the Belfast School of Medicine. Degrees in dental surgery (B D S and M D S) are conferred by the university, and also a diploma in dental surgery (L D S).

#### PROFESSIONAL EXAMINATIONS

The examinations for the M B, B Ch, B A O are four in number. The first deals with (1) inorganic, organic, and practical chemistry, (2) experimental and practical physics, (3) botany and practical botany, (4) zoology and practical zoology. It is divided into two parts, of which botany and zoology form one. The Second Examination covers anatomy and physiology (both theoretical and practical), and may be taken at the end of the second year of the student's career. The Third Examination includes (1) pathology and practical pathology, (2) materia medica, pharmacology, and therapeutics, (3) medical jurisprudence, and (4) hygiene. To be valid a certificate in regard to the study of the subjects of this examination must show that the work has been done after the Second Examination has been passed.

The Final Examination includes (1) medicine, (2) surgery, (3) midwifery, (4) ophthalmology and otology. The student may pass in all subjects at once at the end of his fifth year, or he may divide the examination into two parts—namely, (1) systematic, (2) clinical, practical, and oral. The first part may be taken at the end of the fourth year, but for the second part the candidate may not present himself until the end of his fifth year, but students invariably take both parts at the end of their course. No certificate in regard to the study of the subjects of this examination will be valid unless the work was done subsequent to passing in all the subjects of the Second Examination.

#### THE HIGHER DEGREES

Candidates for the degree of Doctor of Medicine must be graduates in medicine of at least three years' standing, unless they hold also a degree of the university in arts or science, in which case a standing of two academic years will suffice. Moreover, candidates must be able to show that the interval has been passed in the pursuit of such courses of study or practical work as may be prescribed. The degree may be conferred either (a) after a formal examination, or (b) in recognition of the merits of a thesis or of some piece of original study or research carried out by the candidate, followed by an oral or other examination in its subject. When an ordinary examination is imposed it will include (1) a written paper on the principles and practice of medicine, (2) a commentary on a selected clinical case, (3) a clinical and *viva voce* examination, and (4) a written paper and clinical or practical and *viva voce* examination on a subject chosen from the following list: (a) human anatomy, including embryology, (b) physiology, (c) pathology, (d) pharmacology and therapeutics, (e) sanitary science and public health, (f) forensic medicine and toxicology, (g) mental diseases. The regulations for the degrees of M Ch and M A O are of the same general nature.

### NATIONAL UNIVERSITY OF IRELAND

The National University of Ireland carries on most of its educational work through three constituent colleges—one in Dublin, one in Cork, and one in Galway. Each of these provides a full medical curriculum, and all candidates for the medical degrees of the university must pass three of their five years of study at one or other of them. These years do not count except after matriculation or recognition as a student of the Medical Faculty obtained in some other fashion. The candidates at each constituent college are examined by the university, and a common standard of education is secured by all courses of instruction and the regulations concerning them having to be approved by the Senate, after considering report thereon from the Board of Studies of the university. In addition to the ordinary degrees in medicine and surgery, the university grants those of Bachelor and Master of Obstetrics, Bachelor and Doctor of Science in Public Health, and Bachelor and Master in Dental Surgery, as well as Diplomas in Public Health, in Mental Diseases, and in Tropical Medicine.

Application for other information may be made to the Registrar, National University of Ireland, Dublin.

### THE IRISH CORPORATIONS

There are, in the Irish Free State, three licensing bodies other than the Medical Faculties of the universities, and in Dublin, just as in London, there is a Royal College of Physicians of Ireland, a Royal College of Surgeons in Ireland, and in Apothecaries' Hall. In Dublin, as in London and in Edinburgh, the two Colleges have formed an examining Conjoint Board, which is responsible for the recommendation of candidates to the two bodies for their respective licences. The Apothecaries' Hall of Ireland, like the Apothecaries' Society of London, gives its licence separately.

#### THE CONJOINT BOARD IN IRELAND

This body requires of candidates the passage either of its own preliminary examination in the subjects of general education or proof that the candidate has passed one of the tests accepted by the General Medical Council as well as passing in the Pre-Registration Examinations in Chemistry and Physics and Biology.

#### PROFESSIONAL EXAMINATIONS

There are three professional examinations, the first of which cannot be passed earlier than the end of the second winter session, nor the final before the conclusion of full five years of medical study. Before being admitted to any of them the candidate must show that he has studied the deficient subjects in practice and theory for the requisite

periods certificates to this effect being accepted from the authorities of most of the recognized medical schools at home and abroad. The first examination deals with (a) anatomy and (b) physiology and histology. The second examination deals with (a) pathology, (b) materia medica, pharmacy and therapeutics and ophthalmology, and may be taken separately.

**Final Examination.**—This is divided into three divisions which cannot be completed until at least five years have passed in medical studies other than those for the Pre-Registration Examinations and five years at least since the beginning of the curriculum. The divisions are (a) medicine including fevers, mental diseases and diseases of children, (b) surgery including operative surgery, (c) midwifery including diseases of women and newborn children and the theory and practice of vaccination.

**Fees.**—Preliminary Examination £2 2s. Re-examination £2 2s. Pre-Registration Examination £3 3s. Re-examination in Chemistry £2 2s. in Physics £1 1s. First Professional Examination £26 5s. Second £15 15s. Final £6 6s. Re-examination fee is £2 2s. for each division.

### Diploma in Psychological Medicine

There are two examinations in connexion with this diploma. Part I consists of (a) anatomy and physiology of the nervous system, (b) psychology. Part II—(a) neurology, including clinical and pathological neurology, (b) psychological medicine including its legal relationships.

**Fees.**—£3 3s. for each part.

Further information can be obtained from Mr. Alfred Miller, Secretary of the Committee of Management, Royal College of Surgeons, St. Stephen's Green, Dublin.

### ROYAL COLLEGE OF PHYSICIANS OF IRELAND AND ROYAL COLLEGE OF SURGEONS IN IRELAND

#### The Diploma in Public Health

Every candidate for the Diploma in Public Health must observe the following rules:

**Rule 1.** A period of not less than two years shall elapse between the attainment by a candidate of a registrable qualification in Medicine, Surgery, and Midwifery and his admission to the final Examination for a Diploma in Public Health.

**Rule 2.** The curriculum for the Diploma in Public Health shall extend over a period of not less than twelve calendar months subsequent to the attainment of a registrable qualification.

**Rule 3.** Every candidate shall produce evidence of having attended during a period of not less than five months at an institution approved by the Licentiate Board granting the Diploma, practical instruction in—  
(a) Bacteriology and Parasitology (including Medical Entomology) especially in their relation to diseases of man and to those diseases of the lower animals which are transmissible to man;  
(b) Chemistry and Physics in relation to Public Health;  
(c) Meteorology and Climatology in relation to Public Health.

At least 120 hours must be devoted to Course (a) of which not less than 150 hours shall be occupied in practical laboratory work.  
At least 60 hours must be devoted to Course (b) of which not less than 70 hours shall be occupied in practical laboratory work.  
At least 10 hours must be devoted to Course (c).

**Rule 4.** Every candidate shall produce evidence of having received during not less than 20 hours at an institution or from teachers approved by the Licentiate Board granting the Diploma practical instruction in the following subjects:

- The Principles of Public Health and Sanitation (40)
- Epidemiology and Vital Statistics (20)
- Sanitary Law and Administration (including Public Medical Service) (20)
- Sanitary Construction and Planning (10).

(The numbers indicate the normal proportion of time to be given to each subject.)

**Rule 5.** Every candidate shall produce evidence that he has attended for three months on the clinical practice of a recognized hospital for infectious diseases and has received therein instruction in the method of administration. At least thirty daily attendances of not less than two hours in each week shall be required.

**Rule 6.** Every candidate shall produce evidence that he has during a period of not less than six months been engaged in acquiring a practical knowledge of the duties routine and special of Public Health Administration under the supervision of a Medical Officer of Health who shall certify that the candidate has received from this Officer or other competent Medical Officer during not less than three hours on each of six working days practical instruction in these duties and also those relating to—

- Maternity and Child Welfare Service
- Health Service for Children of School Age
- Veneral Diseases Service
- Tuberculosis Service
- Isolation Hygiene
- Inspection and Control of Food including meat and milk

Candidates of having received the prescribed instruction in Public Health Administration must be given by a Medical Officer of Health who lives his whole time to Public Health work or by the Medical Officer of Health of a Sanitary Area having a population of not less than 50,000 or in Ireland the Medical Superintendent Officer of Health of a Sanitary or County Borough having a population of not less than 50,000.

**Rule 7.** The examination for the Diploma shall be divided into two parts Part I and Part II.

**Rule 8.** The examination for Part I shall include the following subjects:

- Bacteriology and Parasitology (including Medical Entomology)
- Chemistry and Physics and Meteorology and Climatology in relation to Public Health

**Rule 9.** The examination for Part II shall include the following subjects:

- Hygiene and Sanitation (including Sanitary Construction)
- Epidemiology and Infectious Diseases
- Sanitary Law and Vital Statistics
- Public Health Administration

The examination shall be written and oral and shall include practical examinations in Infectious Diseases Food in relation Inspection of premises—dwellings factories workshop etc.

### ROYAL COLLEGE OF PHYSICIANS OF IRELAND

Those whose names already appear on the *Medical Register* can obtain the separate Licence in Medicine of this College, and its Licence in Midwifery. In either case an examination has to be passed in the subjects indicated questions on midwifery hygiene, and jurisprudence being included in the examination for the Licence in Medicine. For the Licence in Midwifery practitioners of over five years standing are exempted from examination by printed questions. The other grades of the College are Members and Fellows. The former are admitted after an examination which is open to all university graduates in medicine and Licentiates in medicine of the Royal Colleges of Physicians, and deals with the general subjects of medicine. Fellows are elected, by vote, from among the Members of the College.

**Fees.**—For the Licence in Medicine 15 guineas. Special Examination £21. For the Licence in Midwifery 8 guineas. Special Examination 16 guineas. For the Membership 20 guineas to a Licentiate of the College 30 guineas to others a special examination costs 10 guineas extra. The Fellowship £35 in addition to stamp duty £25.

Information as to special examinations and other matters can be obtained from the Registrar, the Royal College of Physicians, Kildare Street, Dublin.

### ROYAL COLLEGE OF SURGEONS IN IRELAND

This body besides granting a Licence in Surgery, admits those possessed of registrable surgical qualifications to its Fellowship and on certain conditions. Its Licence is usually granted conjointly with that of the College of Physicians but it is given separately to holders of a registrable qualification in medicine provided the College is satisfied that adequate course of study have been pursued and provided its own provisional examination is passed. This examination is held on its behalf by the Conjoint Board and is identical with the ordinary surgical portion of the examination imposed by that body.

**The Fellowship.**—Candidates for the Fellowship must pass two examinations of which the first is in anatomy (including dissections) physiology and histology and the second in surgery (including surgical anatomy) and pathology. Both examinations are partly written partly practical and partly viva voce while the final examination includes the performance of operations. All subjects of either examination must be passed at one time and in neither can a candidate be admitted who has been rejected in any of its subjects by any other licensing body within three months. Candidates are not admitted to the Primary Examination except on evidence that they have already passed an examination in anatomy physiology and histology held by some university or other body whose degrees or licences entitle the holder to admission to the *Medical Register*. However the candidate's name is on the Colonial or Foreign List in the *Medical Register* at the discretion of the Council. Candidates for the final examination must be over 25 years of age produce a certificate of general good conduct signed by two or more Fellows of the College and if successful must make a declaration before admission to the effect that they do not conduct unwholesome practices, and will not do so as long as they are Fellows.

**Fees.**—Candidates for the Licence pay 5 guineas for examination which sum if they pass is counted as part of the fee payable on admission to the Licence this being 25 guineas. Candidates for the Fellowship pay 5 guineas for each examination on the total of 10 guineas being reckoned as part of the fee payable on admission to the Fellowship. That fee is 25 guineas in the case of those who are already Licentiates and 40 guineas in the case of others.

## APOTHECARIES' HALL OF IRELAND

A diploma is granted by this Hall which entitles the holder to be registered as a practitioner of medicine, surgery, and midwifery, and confers also the privileges of an apothecary. Women candidates are eligible.

**Fees**—Primary Examination (Parts I and II) £21; Final Examination £21. Subjects of examination: Primary, Part I, Anatomy and Physiology, Primary, Part II, Materia Medica, including Pharmacy, Medical Jurisprudence and Hygiene, Pathology. Final Examination: Medicine, Surgery, and Midwifery. Candidates must enter for and pass at the one time in Anatomy and Physiology. They are at liberty to enter for the subjects of the Final Examination at separate times, but the final examination cannot be completed until a period of three years has elapsed from the date of passing Primary Examination, Part II.

Application for other information should be made to the Registrar, 95, Merrion Square, Dublin.

## MEDICAL SCHOOLS AND COLLEGES.

## LONDON

INFORMATION as to the fees at each of the various metropolitan medical schools, and the scholarships, prizes, and junior appointments which they offer, will be found in the following pages. The courses they provide are fundamentally the same, and in all of them the arrangements made are such as to meet the requirements of students of every class—of those who are aiming at the diplomas of the English Conjoint Board or the Apothecaries' Society, not less than of those who have London or other university degrees in view. At all, too, special facilities are offered to students who have commenced their professional education at Oxford or Cambridge, and are seeking the medical degrees of those universities.

## CHARING CROSS HOSPITAL

THIS school, with its hospital, is situated in the centre of London, and is easily accessible. Primary and intermediate students attend lectures and practical work at King's College. The final studies are taken in the school and hospital, where systematic lectures, demonstrations, and tutorial classes are arranged to cover all the subjects necessary for the qualifying examinations. Departments are also available for the other final subjects of bacteriology, clinical pathology, biochemistry, materia medica, public health, operative surgery, and for research work. An Institute of Pathology, with a whole-time staff of scientific workers and fully equipped laboratories, has been established in the school. Students receive their training in preventive medicine, pathology, and bacteriology here, and are encouraged to undertake research.

Women students are admitted to the school and hospital upon the same terms and conditions as men, and after qualification are eligible for resident hospital appointments.

**Fees**—The fees are as follows:—Entrance, Primary and Intermediate 10 guineas; Final, 8 guineas; Annual, £40.

Further information may be obtained on application to the Dean of the Medical School, Charing Cross Hospital, London, W.C.2.

## GUY'S HOSPITAL

THE hospital contains 642 beds in constant occupation. Twenty-six beds are set apart for diseases of the eye, and 45 for the most urgent and infammatory medical cases, which form the subjects of case after the Second Lectures. There are special provision of cases of

The final Examination includes (1) midwifery. Beds given, (3) midwifery, (4) ophthalmology and appointments, the student may pass in all subjects at once at the dermatology, fifth year, or he may divide the examination of the genito-urinary—namely, (1) systematic, (2) clinical, and there are oral. The first part may be taken at the end of the year, but for the second part the candidate may not hospital, himself until the end of his fifth year, but students may usually take both parts at the end of their course. No general rule in regard to the study of the subjects of this examination will be valid unless the work was done subsequently passing in all the subjects of the Second Examination. In

the

Wills Library, the departments of chemistry, physics, pathology, and pharmacology, and the school buildings in general, afford opportunities for a liberal education and for research, and provide the full curriculum for a medical qualification. New departments of anatomy, physics, and biology have recently been completed. They are equipped on modern lines, and provide ample accommodation for teaching and research. Special classes are held for the First and Second Examinations for medical degrees of the University of London, for the Pre-Medical Examination, and for the First and Final F.R.C.S. Eng. Special teaching is provided to meet the requirements of the Universities of London, Oxford, and Cambridge in general pathology and pharmacology.

**Appointments**—All appointments are made according to the merits of the candidates, as determined by a committee of the medical staff. Sixteen out-patient officers, eight house-physicians, twenty assistant house-surgeons, eight house-surgeons, four ophthalmic house-surgeons, two genito-urinary house-surgeons, two house-physicians (children's department), and nine resident obstetric assistants are appointed annually. The house-physicians and house-surgeons, obstetric residents, ophthalmic house-surgeons, and genito-urinary house-surgeons hold office for six months each, and receive free board and lodging in the college. Every student is provided with rooms and commons in the hospital during the period of his "take in" as senior dresser. In addition to the clerkships and dresserships in the medical and surgical wards, students are appointed to the posts of clinical assistant, dresser, or clerk in the special departments of ophthalmology, laryngology, gynaecology, diseases of children, diseases of the nervous system, dermatology, otology, actinotherapeutics, anaesthetics, dentistry, orthopaedics, vaccine, tuberculosis, fractures, and genito-urinary and venereal disease, clinical assistantships in the various special departments are open to post-graduates.

**Scholarships, Prizes, etc.**—The following scholarships in Arts and Science are awarded: A Open Junior Science Scholarship (1) An Arts Scholarship of the value of £100, (2) A Science Scholarship of the value of £100, these are awarded annually in June or July. (3) A War Memorial Scholarship of the value of £200, awarded alternately in Arts and Science. This scholarship is open every other year; the next award will be made in July, 1928. (4) A Confine Scholarship in Science. A Junior Science Scholarship of the value of £100 is offered for competition annually in June or July to candidates who have attended the preliminary science classes at this school. Candidates for these scholarships (male students only) must not be under 20 years of age on August 1st of the year of the competition. C Open Senior Science Scholarships: (1) A War Memorial Scholarship of the value of £100, (2) An Open Scholarship of the value of £80, both of these are awarded annually in September. Full particulars as to the scholarships may be obtained from the Dean of the Medical School. Junior prizes for general proficiency, £20, £15, £10, Hilton prize for Dissection, £5, Michael Harris prize for Anatomy, £10, Sands Cox Scholarship for Physiology, £15 for three years, Woodrigo Memorial prize for Pathology, £10, Berney prize for Pathology, £34, Tiersmet's gold medal in Medicine, Treasurer's gold medal in Surgery, and the Golding Bird gold medal and scholarship for Bacteriology (£20), are awarded annually after competitive examination. The Gull Studentship in Pathology of the value of £250 per annum, the Berney Scholarship in Materia Medica of the annual value of about £50, and the Anderson Demonstratorship in Clinical Chemistry, value £150 per annum, are awarded without examination to enable research to be carried on in these subjects. An Arthur Durham Travelling Scholarship of £100 is awarded triennially. The Griffiths Demonstratorship in Pathology of the value of £320 per annum, and the Hilder and Ronald Poulton Fellowship, value £150 per annum, are awarded without examination.

An annual composition fee is paid by all students until a registrable qualification is obtained. Further information may be obtained from the Dean of the Medical School, Guy's Hospital, London Bridge, S.E.1.

## KING'S COLLEGE HOSPITAL

THE medical school of this hospital, which is situated at Denmark Hill, deals with the final examination subjects of the medical curriculum. The hospital was opened in 1917 and is one of the most modern and best equipped in England. The number of attendances in the casualty and out-patient departments during the year 1926 amounted to 223,053. In the education at the hospital a special feature has always been the individual attention given to each student. The studies are co-ordinated under the direction of senior members of the honorary staff, assisted by medical, surgical, obstetric, and pathological tutors.

There are special departments for diseases of women and children, nervous diseases, ophthalmology, otology, laryngology and rhinology, dermatology, radiology and physical treatment. The laboratory and pathological department are especially noteworthy.

**Appointments.**—Sixteen resident medical and surgical officers are appointed half-yearly as well as dressers and clerks in the wards, out-patient departments, *post mortem* rooms, and special departments. Each of the special departments has several clinical assistants. There are three registrars and four tutors, all of whom receive salaries. The Clubs and Societies (I mean combines, athletic, music, and other societies connected with the school) and provide also a common room.

Scholarship, etc.—At entrance Science Scholarship £50 At commencement of Final Studies Anatomy and Physiology Scholarship £50 Pathology and Pharmacology Scholarship £50 Two Merit and 40 Scholarship each £50 a year for 10 years Two Merit and 10 Scholarship each £50 (Oxford and Cambridge student) £50 Coll. Ges. Scholarship £50 Senior Scholarship £10 Todd Prize Tanner Prize—Class Prizes and Medals

Entrance fee of 10 guineas includes membership of the Club and Section Union.

**New Dental School**—This school was opened in October 1923 and provides complete courses for dental degrees and diplomas. The director of dental studies is Dr. A. Livingston, M.B., Ch.B., M.D.S., I.D.S.

The calendar of the school can be obtained on application to the Dean H. Willoughby, Lyle MD JPC or to the Secretary of the West Hill School S C Ranner MA King's College Hospital Denmark Hill SE5

THE LONDON HOSPITAL

This hospital, with its medical college and dental school, is situated in the Mile End Road 1-1. The hospital contains 849 beds, which are in constant use. During 1956 18,077 patients passed through the wards and 129,247 out patient received treatment. Of the latter number, 42,478 received treatment in the departments for diseases of the eye, nose, throat, ear, skin, and teeth and in the pediatric orthopedic, general radiological, electro- and physiotherapeutic and immunization departments. The number of major operations which were performed amounted to 7,873.

The hospital presents therefore a large field for clinical instruction and in its wards and out-patient and special departments exceptional opportunities are afforded for acquiring an extensive and practical experience of all phases of disease.

A clinical unit in medicine, under the charge of a whole-time doctor assisted by an assistant director, two assistants and two house physicians, provides for the more elaborate methods of diagnosis and treatment and takes a leading part in the initiation and co-ordination of medical research. To each medical and surgical firm throughout the hospital there is attached a first assistant who is responsible for instructing the clerks or dressers of the firm in elementary medicine and surgery, and who assists the honorary members of the firm in the preparation of their demonstrations. In the department of obstetrics and gynaecology there are two assistants and two resident accoucheurs. Special courses of lectures and demonstrations are arranged in medicine and surgery and in their ancillary subjects. Opportunities for research are provided under the supervision of the staff.

All the departments are modern and adapted for the teaching of all subjects in the various curricula. Special courses of instruction are held in preparation for the examinations of the University of London for the Fellowship of the Royal College of Surgeons and for the Membership of the Royal College of Physicians. Special entries can be made for the medical and surgical practice of the hospital. To a resident he is provided for the convenience of students. Recent additions to hospital and college buildings include the Dunn Clinical Laboratories, the Beaumont Clinical Theatre, the Barnard Baron Pathological Institute, and a hostel for resident medical officers providing accommodation for forty residents. The athletic ground, of over thirteen acres, is at Hammersmith Park and is open to all members of the Clubs Union.

**Appointments.**—The salaried appointments open to past students of the hospital are those of assistants to the medical unit, first assistants to the medical and surgical firms, obstetric registrar, assistants to the department of obstetrics and gynaecology, medical, surgical, and obstetric tutors, clinical assistants in the medical, surgical, ophthalmic, auril, light and skin, orthopaedic and electrical departments and in the Pathological Institute. There are appointed annually 4 resident physicians, 14 resident house-physicians and 22 resident house-surgeons, 14 resident receiving-room officer, 8 resident emergency officers, 8 clinical assistants to the medical out-patient department, and 16 clinical assistants to the surgical out-patient department, also paid and unpaid clinical assistants in the various special departments. In addition there are numerous assistantship clerkships, and dressership in the departments of medicine, surgery, gynaecology and obstetrics.

**Scholarships and Prizes**—The following is a list of scholarships and prizes: At Entrance: Entrance Scholarship £100; Entrance Scholar ship open to student of Oxford and Cambridge Universities (1) £75 Anatomy and Physiology (2) £100 Pathology Entrance Scholarship in Science £50 Up on Scholarship First Medical Education After Entrance: Buxton Prize in Anatomy and Physiology £0 Leoboly Prize in Organic Chemistry and Medical Pathology £25 Prizes in Clinical Medicine Surgery and Obstetrics and Gynaecology £20 each Duckworth Medal in Clinical Medicine and Surgery £10 Hutchinson Medal in Clinical Surgery £20 Treves Prize in Clinical Surgery £15 Sutton Prize in Pathology £20 A. E. D. Payne Research Scholarship in Pathology £20 Sir Andrew Clark Prize in Clinical Medicine and Pathology £14 T. A. M. Potts (pro re) Prize in Clinical Medicine and Pathology £10 L. Anderson Prize in Elementary Clinical Medicine £20 Dressers Prizes £40 Practical Anatomy Prizes £10 Arnold Thompson Prize in Medical and Surgical Diseases of Children £15 Iddle Prize £120 Francis Farmer Scholarship in Dental Surgery £25 Harold Fink Prize in Dental Surgery £8 £s The London prizes in Dental Surgery and Pathology £5 £s and in Dental Prosthetics £5 5s Seven extra examination prizes each of the value of £3 3s are offered for competition at the end of the courses of lectures in the dental curricula. Funds to the value of over £90 000 permit of financial assistance being given to students and graduates engaged in medical research.

*Fees*—Entrance fee 20 or 15 guineas according to examinations passed annual fee 40 guineas

Full information may be obtained from the Dean at the London Hospital Medical College Mile End E.1

THE MIDDLESBROUGH HOSPITAL

This school and hospital are in Mortimer Street W1 close to Oxford Circus, Goodge Street and Great Portland Street stations. There are a gymnasium, common rooms and restaurant within the hospital premises, and an athletic ground within easy reach. The hospital contains over 450 beds including a wing containing 62 beds for patients suffering from cancer. There are special wards for maternity and gynaecological cases for mental cases for cases of venereal disease and for diseases of children and of the skin and eye.

The medical school which includes the Bland Sutton Institute of Pathology and the cancer research laboratories is completely equipped for teaching the entire medical curriculum including the pre-clinical subjects chemistry, physics and biology. The Bland Sutton Institute under the charge of the Professor of Pathology contains large pathological and public health laboratories, a separate department of biochemistry and smaller rooms for original investigation as well as a pathological and anatomical museum. Bacteriological, clinical and microscopic examinations of material from the wards, operating theatres and out-patient departments are carried out in the laboratories and senior students are eligible for clerkships in connection with this work. Junior assistants in the pathological and bacteriological laboratories are elected annually from recently qualified students. Facilities are given for original research. The cancer research laboratories offer unparalleled opportunities for the study of this disease in both its clinical and pathological aspects.

**Appointments.**—Twenty-two resident appointments are open annually for competition among students of the hospital. The officers sit at and board in the residential college free of expense. Two casual medical and two casual surgical officer and two resident officers to the special departments, are appointed annually. Eight house-

surgeons are appointed every year at intervals of two months, after examination six house-physicians are also appointed annually at similar intervals. In obstetric and general medical house-surgeon is appointed every six months. Nine registrars are appointed annually. In the out-patient departments the appointments are clerk and dresser to the physicians and surgeons to out-patients, clerk in the departments for diseases of the skin and venereal diseases, dressers to the department for diseases of women, to the ophthalmic surgeon, to the throat and ear department, and to the dental surgeon. Extern midwives, clerks and post-mortem clerks are also appointed. The appointments are so arranged that every student may, during his course, hold all the out-patient and in-patient clerkships and dresserships. Students must have held an out-patient clerkship and dressership before holding in-patient clerkships or dresserships. Non-resident qualified clinical assistants are appointed in the medical, surgical, skin, neurological, ophthalmic, throat and ear, odontological, children's and electro-therapeutic out-patient departments.

**Scholarships.**—There are two Entrance Scholarships, value £100 each. Two annual Entrance Scholarships, of the value of £90 and £60 respectively, are open to students of the universities of Oxford and Cambridge who have completed the curriculum for, or passed the examinations in, anatomy and physiology. Students joining the school in the previous April are eligible. The Peter Lucas Scholarship is annually awarded on the nomination of the headmaster to a pupil of Epsom College who has passed the first examination for medical degrees (Preliminary Scientific Examination). There is also a scholarship, value £50, awarded annually to students from New Zealand. In addition to the Entrance Scholarships, there are numerous other valuable scholarships, prizes, and exhibitions open to students of the hospital, including the Brodrip Scholarships, value £60 and £40. Lyell Gold Medal and Scholarship, value £55 5s., Freeman Scholarship, value £30, John Murray Gold Medal and Scholarship, value £25, Hetley Clinical Prize, value £25, Leopold Hudson Prize, value 11 guineas, and the Second Year's Exhibition, value 10 guineas.

The rebuilding of the hospital is being carried out without the loss of a single bed, or any disorganization of its clinics.

**Fees.**—(a) For medical students. For one year or less, £21. (b) Students who have completed the Preliminary Science course. Entrance fee, 25 guineas, five annual fees of £45. The annual fee for further attendance at the medical school if a registrable qualification has not been obtained, is £25. Three quarters, one half, or one quarter of the first annual fee may, at the discretion of the School Council, be returned if the student obtains a registrable qualification within three six, or nine months of the annual payment becoming due. (c) Oxford and Cambridge and other students who have completed the Intermediate course. Entrance fee, 15 guineas, two annual fees of £45, five annual fees as above. These fees are inclusive and cover the cost of instruction in vaccination, fevers etc. and also the subscription to the amalgamated clubs and hospital journal.

Further information may be obtained from the Dean or the School Secretary.

### ST BARTHOLOMEW'S HOSPITAL

THIS institution fills one side of Smithfield and Giltspur Street, covering the greater part of a large island of ground separated practically from all other buildings, it is on the edge of the City, and easily reached from all parts of London. The hospital contains 757 beds. Extensive buildings, opened in July, 1907, occupy part of the ground required from the old Bluecoat School, and these mutually enhance the attractions of the hospital as a place of medical study. The medical school buildings, including the library, the museum, and the chemical, biological, and anatomical departments, have now at their side a very large building, which includes club rooms for the Students' Union, a visiting room, luncheon and dining halls, new quarters for the resident staff, and an out-patient department and accommodation for special departments of such large size as to be unsurpassed by any hospital in the kingdom. During the year 1909 a second block of new buildings was completed. These form the pathological department, and include, in addition to an extensive post-mortem room, large and well equipped laboratories for clinical pathology, pathological histology, bacteriology, and chemical pathology, altogether forming the most complete pathological department in the country. A further large block in Giltspur Street was required in 1923, and has been equipped by the construction of new lecture theatres and extensive laboratories for physics, chemical physiology, experimental physiology, histology, and pharmacology. The Students' Union owns grounds of some ten acres in

extent for recreative purposes at Wynchmore Hill, which is easily accessible from the hospital.

Special classes are held for students preparing for the Preliminary Scientific and other examinations, for the M.B., M.D. of the Universities of Oxford, Cambridge, and London, and for the higher surgical degrees at the same universities, including the M.Ch. Oxon., M.Ch. Cantab., M.S. Lond., and F.R.C.S. Eng.

**Clinical Units.**—Special clinical units have been established in medicine and surgery, each under the charge of a professor and director who devotes the whole of his time to the purpose of hospital practice, teaching, and research. In each unit there are an assistant director and four assistants, for whom special laboratory accommodation has been provided by a gift from the Sir William Dunn Trustees. The appointments of clerks and dressers are open to all students in these departments, and arrangements are made for all students to study in these units during a part of their clinical course.

**Appointments.**—Clinical clerks to the physicians and to the physician-reconneur, and dressers to the surgeons and in the casualty department, are chosen from the students, clerks and dressers are also selected from the students to attend in the out-patient rooms, in the special departments (ophthalmic, othopredic, gynecological, children's, laryngological, urological, dermatological, venereal, electrical and dental, and in the post-mortem room. Chief assistants and clinical assistants are selected from qualified men appointed yearly to help in the general medical, surgical, and in special departments. Ten house-physicians and ten house-surgeons are appointed annually. During their first six months of office they act as "junior" house-physicians and house-surgeons and receive a salary of £80 a year. During their second six months they become "senior" house-physicians and house-surgeons, and are provided with rooms by the hospital authorities, and receive a salary of £80 a year. A resident midwifery assistant, an ophthalmic house-surgeon, a house-surgeon to the skin and venereal department, and a house-surgeon for diseases of the throat, nose, and ear are appointed every six months, and are provided with rooms and receive a salary of £80 a year. Three resident administrators of anaesthetics are appointed—the senior for one year at a salary of £150, and two juniors for six months with a salary at the rate of £80 per annum—and all are provided with board and rooms. An extern midwifery assistant is appointed every three months, and receives a salary of £80 a year.

**Scholarships.**—Four Entrance Scholarships are annually awarded after examinations held in September. The subjects of examination and conditions of eligibility for these scholarships are: (1) One scholarship, value £75, in not fewer than two and not more than three of the following subjects: chemistry, physics, botany, zoology, physiology, pathology, and anatomy, limited to students under 25 years of age who have not entered on the medical or surgical practice of any London medical school. (2) One scholarship, value £100, in not fewer than three of the following subjects: chemistry, physics, botany, zoology, and physiology, limited to students under 21 years of age who have not entered on the medical or surgical practice of any London medical school. (3) An entrance scholarship in arts, of the value of £100, in Mathematics, Latin or Greek, or French or German, a second language or Chemistry or Physics. (4) The Jefferson Exhibition in the same subjects as No. 3—of the value of £50. Candidates for Nos. 3 and 4 must be under 19 years of age. The total value of the scholarships and prizes is over £1,200 annually.

Further information and a handbook can be obtained on application to the Dean of the Medical College, St Bartholomew's Hospital, E.C.1.

### ST GEORGE'S HOSPITAL

THIS school is at Hyde Park Corner, and is carried on in connexion with St George's Hospital, an institution having a service of 426 beds, of which 100 are at the convalescent hospital at Wimbledon. It provides for the instruction of its students in the preliminary and intermediate subjects of the curriculum at the teaching centre of London University established at King's College. The school at Hyde Park Corner is devoted entirely to the teaching of clinical subjects, great attention being paid by the members of the staff to individual teaching. A number of special courses are given, in which the requirements of universities and all other examinations receive careful attention. The St George's Hospital Club consists of an amalgamation club, with smoking and luncheon rooms on the hospital

promote and offer students alike with an athletic ground at Wimbledon. Students have the advantage of a well-filled library of medical and scientific books. A register of accredited practitioners and a list of medical men and others willing to receive St. George's men as boarders may be seen on application to the Dean.

**Appointments.**—Two house-physicians, two house-surgeons and two casualty officers are appointed every two months. The house officers reside and board in the hospital free of expense. The casualty officers are non-resident, and receive salaries at the rate of £100 per annum. After the student has held a house appointment the following are, among others, open to him: assistant resident physician at £350 per annum, assistant resident surgeon at £350 per annum, medical officer to the Atkinson Morley Convalescent Hospital at £300 per annum, medical registrarship at £200 per annum, surgical registrarship at £200 per annum, medical officer to the biochemical department at £100 per annum, assistant curatorship of the museum, £100 per annum, obituary assistantship, resident at £50 per annum, the post of resident anaesthetist at £100 per annum, the posts (three) of junior anaesthetist, each at £50 per annum.

**Scholarships.**—The following Entrance Scholarships and Exhibitions in anatomy and physiology and in general pathology are awarded in July to candidates who have passed the second M.B. London or corresponding examination: Senior William Brown Exhibition of the value of £150, Senior Scholarship of the value of 90 guineas, Junior William Brown Exhibition of the value of £50, Junior Scholarship of the value of £70, David Pendlebury Scholarship of the value of £50 and Exhibitions each of the value of £40 and up to six in number. Other prizes to the value of £200 are awarded annually to the students of the hospital.

**Fees.**—First year (First M.B. or pre-medical course) £36 15s. second and third years £42 each. For the course of clinical study in the fourth and subsequent years entrance fee £10 10s. annual composition fee £42. No entrance fee payable by St. George's students who have studied at King's College.

Further information may be obtained from the Dean of the Medical School.

#### ST MARY'S HOSPITAL

This hospital and medical school are situated close to Paddington Station (G.W.R.), lying on one side a poor district of 500,000 persons, and on the other side the residential district of Kensington and Bayswater. The hospital contains 283 beds, and extensions at present in progress will raise this number to 334 and provide two new operating theatres. By a scheme of affiliation, for teaching purposes, of several neighbouring hospitals the teaching facilities extend over 1,000 beds. By arrangement with the Lock Hospital, students take the course of instruction in venereal diseases there. The athletic ground (ten acres) is situated at Fembles, and can be reached in twenty minutes by a constant service of trains.

**Clinical Facilities.**—Clinical units in medicine and surgery were established in 1920, and have now been formally recognized by the University Grants Committee. St. Mary's being one of the six medical schools in London which enjoy this privilege. In addition to the king in beds at St. Mary's every student attends a short course at Queen Charlotte's Maternity Hospital (which is situated near to St. Mary's) before holding a post on the maternity district of the hospital.

**Institute of Pathology and Research.**—Students specially interested in pathology and bacteriology have singular advantages at St. Mary's. The Institute comprises seven special departments, the whole being under the personal direction of Sir Almroth Wright, F.R.S. Research scholarships of £200 each are awarded annually to students working in the departments of the Institute and research beds are provided. Clerkships in pathology and bacteriology and chemical pathology, lasting for a period of three months are open to students of the fifth year and enable them to carry out the pathological and bacteriological investigations of the wards, and learn the necessary technique under supervision. Seventy-two of these posts are available annually. Numerous appointments are open to newly qualified members of the medical school including ten elevated posts, with salaries varying from £200 to £750 per annum.

**Complete Curriculum.**—The medical school provides complete courses of instruction, and students can join at once

on passing a Preliminary Examination in Arts. Terms begin in October, January, and April.

**Entrance Scholarships.**—Two Entrance Scholarships of £210 each and one of £25 5s. are awarded annually in July by nomination on the lines of the Rhodes Scholarship. The Geraldine Harmsworth Scholarship (£200) and one or more University Scholarships of £200 are awarded annually in July.

**Fees.**—Composition fees for entire curriculum (5½ years) £200 in one sum or £210 by five annual instalments. Composition fee for clinical curriculum (2½ years) 90 guineas in one sum or 55 guineas by two annual instalments. As an alternative students may pay an annual fee of 40 guineas with an entrance fee of 10 guineas.

#### ST THOMAS'S HOSPITAL

This school and hospital are situated in Lambeth on the south bank of the Thames, facing the Houses of Parliament and form one of the well-known architectural features of London.

The school buildings which are separated from the hospital by a quadrangle comprise lecture theatres, laboratories, and classrooms well adapted for the modern teaching of large bodies of students in the subjects of the medical curriculum. A splendid library and reading room and a complete museum are open to all students from 9 a.m. to 5 p.m., on Saturday to 1 p.m. St. Thomas's House, the new Students' Club recently opened comprises spacious dining and club rooms, etc., and provides accommodation for some sixty resident students. The terrace affords facilities for exercise and recreation. The sports ground of more than nine acres in extent is at Chiswick. It can be reached in forty minutes from the hospital, it is admirably adapted for football, cricket, lawn tennis, and athletic sports.

The hospital proper contains 644 beds. In addition to the ordinary provisions of a great hospital there are connected with the out-patient department physicians' and surgeons' rooms provided with ample sitting accommodation, so that students are enabled to follow closely the practice and teaching of the out-patient staff. There is a full complement of special departments, and connected with the hospital a special tuberculosis department gives opportunity for instruction of students. There is a clinical theatre centrally situated so as to facilitate the illustration of lectures by patients from the wards and out-patient room, it is arranged also for lantern demonstrations. The maternity ward contains 21 beds gives students full facilities for maternity training under supervision within the precincts of the hospital. This overrules any necessity for supplementary instruction elsewhere and fully prepares the student for the external maternity practice of the hospital district. The revised regulations of the examining bodies can thus be fully complied with.

**Appointments.**—All hospital appointments are open to students without charge. A resident physician, a resident assistant surgeon and a resident anaesthetist are appointed annually at a salary of £265 each per annum. Two hospital registrarships (medical and surgical) at an annual salary of £250 each are appointed annually. The tenure of these offices may be renewed for a term not exceeding two years. A pathological registrar to the department of obstetrics and gynaecology (at an annual salary of £250), an ophthalmic registrar (at an annual salary of £50) and an orthopaedic registrar (unpaid) are appointed yearly. Ten resident casualty officers and anaesthetists (including two senior) are appointed every six months. Six house-physicians (including two obstetric house-physicians and one house-physician to the department of diseases of children) and nine house-surgeons (including two ophthalmic house-surgeons, one orthopaedic house-surgeon, and two house-surgeons to the ear, nose and throat department) are appointed every six months. Thirty-six or more clinical assistants in the special departments are appointed every three months, and hold office for six months if recommended for re-election. Clinical clerkships and dresserships to the in-patient and out-patient departments are available to the number of 400 each year.

**Scholarships.**—There are five Entrance Scholarships, two in arts giving one year's free tuition, one of £150 and one of £50 in chemistry, physics and biology for students who have no received instruction in anatomy or physiology, one of £100 in any two of the following subjects: anatomy, physiology, chemistry or

pathology for students who have completed their examinations in anatomy and physiology for a medical degree in any of the universities of the United Kingdom or the Colonies and have not entered as clinical students in any London medical school. The money value and subjects of examination of the remainder are as follows: (a) William Tite Scholarship for second year students, £25; (b) and (c) Musgrove Scholarship or (alternately) Perceval Scholarship each for third year students and tenable for two years £35 each; (d) Merd Medal Medicine, Pathology, and Hygiene; (e) Wainwright Prize, Medicine; (f) Toller Prize, Medicine; (g) Cheselden Medal Surgery and Anatomy; (h) Clutton Memorial Medal in Clinical Surgery, biennial; (i) Bennet Scholarship £50 biennially Surgery and Surgical Pathology; (j) Solly Medal and Prize, biennially, Reports of Cases; (k) Sutton Sims Prize biennially, Reports of Cases; (l) Bristowe Medal, Pathology and Morbid Anatomy; (m) Hadden Prize Pathology and Morbid Anatomy; (n) Granger Testimonial Prize, £31 10s Anatomy and Physiology; (o) Louis Jenner Research Scholarship tenable for two years £60 annually, Pathology; (p) School Council Research Scholarship £250 per annum; (q) John and Temple Research Scholarship value £450 per annum (children).

**Fees**—The annual fees are: For each year of study, £50. These fees cover all tutorial classes, but do not include instruction in infectious fever, pharmacy and vaccination. A limited number of qualified practitioners are permitted to attend the hospital practice on terms which may be ascertained from the Medical Secretary.

Special courses of instruction are given for various examinations, and a register of lodgings is kept at the school. Further information may be obtained from the Medical Secretary of the School, St. Thomas's Hospital, Albert Embankment, S.E.1.

#### UNIVERSITY COLLEGE HOSPITAL

The school, which forms part of the corporation of University College Hospital, is in immediate proximity to the hospital in University Street, and opposite University College. It comprises departments of medicine, surgery, midwifery and gynaecology, pathology including morbid anatomy, chemical pathology, biochemistry and bacteriology, radiography, forensic medicine, mental physiology and mental diseases, dental surgery, practical pharmacy, and other departments for the study of special diseases, such as those of the eye, skin, ear and throat, venereal diseases, and for instruction in anaesthetics, electrotherapeutics, and skiagraphy. The Hospital and School have acquired the National Dental Hospital and College as their dental department thus providing every facility for the study of dental subjects. The Royal Eye Hospital has also been amalgamated with the Eye, Nose, and Throat Department, and a new hospital for in- and out-patients, close to University College Hospital, is completed.

The school thus provides the final course of study for the degrees of the Universities of Oxford, Cambridge, London, Durham, and other British universities, and for the diplomas of the Royal Colleges of Physicians and Surgeons in Medicine and Dental Surgery and the Licentiate of the Society of Apothecaries. Special bacteriological classes are also held in preparation for the various diplomas in public health. Each department is also equipped for more advanced work, and provides facilities for research.

Clinical units in medicine, surgery, and obstetric medicine are now in operation. The whole-time directors of the units are concerned with the organization of the teaching generally, but the honorary staff is responsible for the largest share of the teaching in the wards and out-patient department of the hospital.

The new buildings of the obstetric hospital of 60 beds (rendered possible by the Rockefeller benefaction), the new Residents' House (with accommodation for 30 residents and students), the extension of the Nurses' Home, and the new research laboratories for the Medical School, are now finished and in full occupation.

**Appointments**—The qualified appointments, in addition to a number of posts as house-physicians and house-surgeons and obstetric assistants, include the appointments of resident medical officer, medical registrar, surgical registrar, obstetric registrar, Haiker Smith and junior registrar, ophthalmic registrar, casualty medical officers, casualty surgical officers, assistants in ear, nose and throat, skin and venereal diseases departments, and house anaesthetists.

**Scholarship**—The following scholarships and prizes are open to competition. Two entrance Exhibitions of 112 guineas each, awarded after a competitive examination in Anatomy or Physiology or General Pathology. Radcliffe Crocker Travelling Scholarship in dermatology for one year, value about £220. The Graham Scholarship in pathology of a sum not exceeding £400 per annum,

Leslie Pearce Gould Research Scholarship in surgery for one year, value about £200. The Atkinson Moyley Scholarship of £45 a year for three years, awarded after examination in the theory and practice of surgery, the Atkinson Scholarship of £55 a year for two years for general proficiency in medical studies. The Magrath Clinical Scholarship, value about £150. The Illiter Exhibition in pathology of £30. The Percival Allyn Prize for the advancement of surgery by research, value about £75. The Graham Gold Medal for research work, four Fellows Medals in clinical medicine, four Medals in clinical surgery, the Bruce Medal in pathology, and surgery, two Tuke Medals in pathology, and the Irichen Prize for practical surgery.

**Fees**—The fee for the full course of final studies at the school is 112 guineas if paid in one sum, or 115 guineas if paid in two instalments. Fees for vaccination, fevers and pharmacy not included.

Patricians of general and special courses can be obtained on application to the Dean of the Medical School, University College Hospital, University Street, W.C.1.

#### WESTMINSTER HOSPITAL

This school, with its hospital, situate in Broad Sanctuary, opposite Westminster Abbey, provides for the education of its students in the preliminary and intermediate subjects of the University of London at King's College. The rest of the work is done in the school buildings near the hospital. The number of in-patients averages 3,500 and out-patients upwards of 30,000 annually, and the hospital and school afford ample facilities for instruction in all branches of medicine and surgery.

**Appointments**—A medical and surgical registrar are appointed annually, each with a salary of £150, and an obstetric registrar with a salary of £50. A senior resident and casualty officer, salary £104 per annum and board, appointed for six months, may be extended for a further period of six months. Three house-physicians, three house-surgeons, three assistant house-physicians, three assistant house-surgeons, and a resident obstetric assistant are appointed after examination, and are provided with rooms, commons, and salary of £52 per annum, except the assistant house-physicians and the assistant house-surgeons, who are provided with commons only. The assistant house-physicians, after three months' service, become house-physicians for a further period of six months, and the assistant house-surgeons, after three months' service, become house-surgeons for a further period of six months. Two house-anaesthetists are appointed for three months, non-resident, salary £50 per annum. Clinical assistants to the assistant physicians and assistant surgeons, and to the officers in charge of special departments, are appointed from among the qualified students. Every student must perform the duties of out-patient dresser for three months and afterwards hold the office of in-patient dresser for three months. He is also required to serve two terms of three months each as medical clinical clerk to the in-patient physician and one term as gynaecological clinical clerk. Two pathological clerks are appointed every three months to assist in the post-mortem room. No student is eligible as an in-patient dresser or clinical clerk until he has passed the Second Examination of the Conjoint Board, or an equivalent examination. Clerks and dressers in the special departments of hospital practice are periodically appointed. So far as vacancies permit, students of other hospitals are admitted to in-patients' dresserships or clerkships.

The governors of the hospital have now completed the extensive improvements and alterations to the hospital, which render it a still more efficient teaching institution, with an increased number of beds.

The athletic ground is situated at Tooting, and can be reached in twenty minutes from the hospital.

**Scholarships**—The following open scholarship are offered for competition during the year 1927-28. In the winter session 1927-28 scholarships in anatomy and physiology £75 each. In the spring two scholarships in anatomy and physiology £75 each. A certain number of scholarships have been allotted to universities of England, Wales and the Colonies, and to public schools. These scholarships are awarded entirely on the nomination of the Principal of the university or school.

**Fees**—The annual composition fee is £40. An entrance fee of 10 guineas is payable by all students—namely primary and intermediate students £10 10s. Students entering for the final year £8 8s. These fees include subscriptions for membership of the Clubs Union.

Further information and a prospectus can be obtained on application to the Dean at the Westminster Hospital, Westminster S.W.1.

LONDON (ROYAL LIRIC HOSPITAL) SCHOOL OF MEDICINE  
FOR WOMEN

The school is situated at 8 Hunter Street Binswick Square W.C.1 close to the Royal Free Hospital. It is like all the other London schools which have so far been mentioned one of the constituent schools of London University. The laboratories are extensive and well lighted, and are fully equipped for the examination courses of the University of London and the Royal Colleges of Physicians and Surgeons. Research laboratories are attached to all departments. A large well equipped library, common room, union room and refectory are provided for the use of students. Resident accommodation for 60 students is provided in students' chambers attached to the school.

The Royal Free Hospital, Gray's Inn Road, W.C.1 has 245 beds, all of which are available for clinical instruction. A new block contains the obstetrical and gynaecological unit which controls 68 beds. A large maternity district is served from the unit with a separate maternity hostel in the Essex Road, Islington. There are separate departments for diseases of the eye, ear, and skin, children and infant welfare, venereal diseases, orthopaedic surgery, massage, light electrical and x-ray work, dentistry and casualty. The instruction given covers the full curriculum for the M.B. B.S. degrees of the University of London, including first medical courses. Students attend the practice of one of the fever hospitals of the Metropolitan Asylums Board and receive special instruction in lunacy at Bethlem Hospital; they are also admitted to the practice of a number of special hospitals, and hold clerkships and dresserships at the Elizabeth Garrett Anderson Hospital, the Cancer Hospital, the National Hospital for Nervous Diseases, the South London Hospital and the Royal Ophthalmic Hospital. The work of the school includes preparation for the Primary Fellowship examination, and also for the Medical School and general hospital course for dental students.

**Appointments**—Qualified students of the school can obtain appointments as house-physicians and house-surgeons, obstetric assistants, surgical gynaecological and medical registrars, assistant pathologists, assistant anaesthetists, medical electrician, shrinker, and clinical assistants and demonstrators in various subjects.

*Scholarships*.—The Isabel Thorne Entrance Scholarship value £30 the St Dunstan's Medical Exhibition value £60 a year for three years which may be extended to five years; the Alfred Langton Scholarship of £50 a year for two years; the Flora Murray Bursary of £50 and the Mabel Sharmman Crawford Scholarship value £20 a year for four years are offered for competition in each year. The Sir Owen Roberts Memorial Scholarship of the value of £75 a year for four years; the Mr George J Smutts Scholarship of the value of £50 a year for three years which may be extended to five years; the Dr Margaret Todd Scholarship of the value of £57 10s. a year for four years; and the Sarah Holborn Scholarship of the value of £20 a year for three years which may be extended to five years are awarded in alternate years. The School Jubilee Bursary of £59 a year or three years is offered every third year. The Boeckel Scholarship value £50 a year for two or four years is awarded by the Reid Trust Co., on the result of an examination held in May by the University of London every fourth year. The holder of the scholarship must enter the London School of Medicine for Women. The Lieutenant Edmund Lewis and Lieutenant Alexander Lewis Memorial scholarships of the value of £25 a year for ten years is awarded every fourth year. The John Byron Bursary of £28 a year for two years; the Julia Anne Hornblower Cook Prize of £60 the Helen Pridaux Prize of £60 the Mabel Webb Pearce Scholarship of £30 for two years; the Fanny Butler Scholarship of £16 a year for four years together with many other scholarships and prize are offered on sundry conditions.

The Dr Edith ...uate Scholarship of £100 is awarded annually to offer women who wish to go to India and other countries as medical missionaries.

**Fees**—Courses for the University of London degrees and the diplomas of the Conjoint Board in England and other qualifications £2.0 payable in five instalments. These sums include library and laboratory fees.

The Students Union exists to promote corporate action of the student on matters of common interest to promote and maintain athletic and other clubs and to issue a school magazine. All students are required to become members of the Union. The students sports ground which consists of a freehold property of seven and a half acres is situated at Sudbury.

Further information can be obtained from the Warden and Secretary

## KING'S COLLEGE

In the result of Medical Science instruction is given in the preliminary and intermediate subjects of the first and second examinations leading to the degree of M.B., B.S. of the University of London of the corresponding examinations of other universities and of the Conjoint Examining Board of the Royal Colleges of Physicians and Surgeons, including the primary examination for the I.R.C.S. Eng. The courses are open to women students on the same terms as to men.

Regular students who have completed their preliminary and intermediate examinations proceed to hospital to pursue their studies for the final examinations. The hospitals associated with King's College are King's College Hospital, Darnley Hill S15 Westnminster Hospital & W1 St George's Hospital Hyde Park Corner, SW1 and Charing Cross Hospital Strand W C2

A course for the degree of the University of London and for the Diploma of the Royal College of Surgeons in dental surgery in conjunction with King's College Hospital Medical School has been arranged.

*Scholarships*.—The entrance Scholarships are (1) Two Warneford Scholarships each £50 for four years subjects—selected from mathematics classics divinity and science (2) One Sambrook Scholarship of £30 for three years subjects of examination selected from mathematics classics and science. The holders of the preceding awards must proceed to Kings College Hospital (3) Worsley £100 paid in five annual instalments (4) Rabbeth Scholarships value £30 and £15 in July for the best student of the first year (5) Second years scholarship value £20 for the best student of the second year (6) Daniell Scholarship £40 awarded on the results of the University Honours Examination (7) The Layton and Berridge Studentships each £150 per annum and (8) numerous prizes.

Full information as to admission fees and scholarships can be obtained from the Dean of the Faculty of Medical Science  
King's College Strand W C2

## UNIVERSITY COLLEGE

This institution one of the principal component parts of the University of London, possesses a Faculty of Medical Sciences whose work covers all the subjects included in the group commonly known as the preliminary medical sciences—namely, physics, chemistry, botany, and zoology, and also the intermediate medical science—namely, anatomy, physiology, and pharmacology. The new anatomy building provided by the munificent gift of the Rockefeller Foundation of New York, was opened on May 31st, 1923 by His Majesty the King. This building forms part of the block which includes physiology and pharmacology. The department of hygiene and public health prepares for the diplomas in public health of the Royal Colleges and of the various universities. Research work is undertaken in all the above named departments. The College undertakes the education of students in all the subjects mentioned leaving them free to complete their education in the strictly professional subjects—medicine, surgery, and the like—at any one of the recognized schools of advanced medical studies. The work is somewhat differently arranged, according to whether the student has in view the degree of the University of London or the diplomas of the Royal Colleges. In either case the whole work to be done is divided into courses devised to meet the requirements of different examinations, and students can join the College for any of them. Women students are admitted to all courses on the same terms as men. The general arrangements for the benefit of students include membership of the Union Society or the Women's Union Society with the College gymnasium and the athletic grounds. There is also a collegiate residence for about fifty-five men students at Ealing and for about seventy women students at Byng Place, Gordon Square.

**Scholarships**—The scholar hips and exhibition obtainable include the Bue' mill Scholarship value £150 gun a in chemistry, physics botany and zoology (the successful student must complete his work at University College Hospital Medical School) two entrance exhibitions in the same subjects each of the value of 55 guineas and a Faculty of Medical Sciences Entrance Scholarship value £30 a year for three years

**Fees.**—The fees for the courses covering the work of the First Examination for medical degree of the University of London, and in both parts of the Second Examination amount to 115 guinea. The fees for the courses covering the corresponding examinations

with the salary will be at the rate of £160 per annum, with board apartments and laundry. From the resident medical officers a senior resident medical officer is appointed at a salary of £200 per annum. At the Bristol General Hospital a senior resident medical officer, £250 per annum, resident house-physician, £80 per annum, two house-physicians £80 per annum, house-surgeon £80 per annum, resident obstetric officer, £80 per annum, house-surgeon to special department, £60 per annum, dental house-surgeon (non-resident) £50 per annum. All these appointments are for six months, except that of senior resident medical officer which is for two years.

**Scholarships**—The following are among the scholarships and other awards open to students of the school: The Ashworth Hallett Scholarship value £40 open to women on the two Martin Memorial Pathological Scholarships of £10 each; the Tibbits Memorial Prize value 7 guineas for proficiency in practical surgery; the Committee's Gold and Silver Medals for fifth year students for general proficiency; the Augustin Richard Prize value about 6 guineas for proficiency in anatomy; the Henry Clark Prize value 11 guineas for proficiency in gynaecology; the Croxby Leonard Prize value 6 guineas for proficiency in surgery; the Supple Surgical Prize a gold medal and 7 guineas; the Supple Medical Prize a gold medal and 7 guineas; the Henry Marshall Prize value £12 for dressers; the H. M. Clarke Scholarship value £15 for proficiency in surgery; the Sanders Scholarship value £22 10s for general proficiency; the Barrett-Rouse Scholarship for proficiency in diseases of the nose, throat and ear; or skin value £17; Lady Hafield Scholarship value about 25 guineas; Phyllis Siepmann Prize for proficiency in diseases of children value £25; Bristol City Senior Scholarships and the Senior Scholarship offered by the counties of Gloucestershire, Somerset, Wilts, Devon etc. are tenable in the university.

Son of the Fellows' ps awarded by the Colston Research Society for research in the university are allotted to the Faculty of Medicine.

**Fees**—The fee for all the course required for the medical curriculum including hospital practice is 205 guineas paid by annual instalment.

#### UNIVERSITY OF DURHAM COLLEGE OF MEDICINE

THIS, the Medical School of the Faculty of Medicine of the University of Durham is in the neighbouring city, Newcastle-on-Tyne. Its classes and lectures are arranged to meet the requirements of the university in all the degrees (other than Hygiene) which the latter grants, and also those of the other examining bodies. The students do their work in the preliminary sciences at Armstrong College also part of the university, and their clinical work in the Royal Victoria Infirmary, an institution with more than 550 beds and special accommodation for the benefit of students. Students do their practical midwifery at the Princess Mary Maternity Hospital, which contains 80 beds, thoroughly up to date, and there is an annual indoor and outdoor attendance on 3,000 cases. In a Heath wing of the school itself there is the department of physiology. There are also in this wing a gymnasium and a set of rooms for the use of the Students' Union. A new bacteriological department has been erected adjacent to Armstrong College.

**Post-Graduate Instruction**—A comprehensive series of post-graduate courses has been arranged to enable practitioners to take advantage of the facilities for laboratory work and clinical study which are afforded by the College, the Royal Victoria Infirmary, and other associated hospitals and in order to meet the varied requirements of practitioners there are general and special courses in the winter and summer session as well as an intensive course in the summer vacation.

**Students' Union**—Students' Union Buildings have been erected and furnished at a cost of over £40,000 and are now in daily use. Separate accommodation (non-residential) is provided for men and women students.

**Appointments**—Pathological assistants, and assistants in the eye department, throat and ear department, and department for skin diseases, are elected periodically. Clinical clerks and dressers are appointed every three months.

**Scholarships**—University of Durham Entrance Scholarship £25 a year for four years; Pease Entrance Scholarship £20 a year for three years (awarded every third year); Province of Durham Masonic (Entrance) Scholarship £20; Heath Scholarship for surgery £200 available every second year; Petherford Memorial Surgical Scholarship £120 available every third year.

The following scholarships are tenable for one year—namely: Tulloch Scholarship for elementary biology and organic chemistry; £20 Dickinson Scholarship for medicine surgery midwifery and

pathology; Gold Medal and £20 Clariton Scholarship for medicine; £25 Gibb Scholarship for surgery; £25 Luke Armstrong Scholarship for co-surgery; £25 Scott Scholarship for highest marks in Gordon Memorial Scholarship for clinical medicine and clinical surgery interspersed on £225 Gibb on Prize for midwifery and diseases of women and children; £10 Turnbull Prize and Silver Medal for surgery anatomy; Outram Wood Prize for psychological medicine; £10 and Sewell Memorial Prize and Silver Medal for clinical pathology. At the end of each session a prize of books is awarded in each of the regular classes.

**Fees**—The composition fee for lectures at the college is £1-0. Composition fee for hospital practice, £16 plus £2 2s yearly for three years payable to the Committee of the Royal Victoria Infirmary. Other information should be sought from the Registrar of the College of Medicine at Newcastle.

#### LIVERPOOL

THE School of Medicine—which is open to both male and female students—in this city forms the teaching centre of the Medical Faculty of the University of Leeds, and is situated in immediate proximity to the General Infirmary where students sufficiently advanced receive their clinical instruction. The buildings were opened in 1884 and contain excellent dissecting rooms, well arranged laboratories for physiology, pathology and bacteriology, three lecture theatres and several similar classrooms. In addition there are a library and reading room and two museums, one being devoted to pathology and the other to anatomy. The comfort of the students is secured by common rooms and a refectory in which they can take meals. The General Infirmary has 632 beds and includes gynaecological and ophthalmic wards, a special children's ward and a large out-patient department. The Ida and Robert Arthington Semi-convalescent Hospitals, Cookridge attached to the infirmary, have 88 beds. The West Riding Mental Hospital at Wakefield is open for the study of mental diseases. Students can in addition attend the practice of the Leeds Public Dispensary, the Hospital for Women and Children, and the Leeds Maternity Hospital, where the obstetric work is done.

**Appointments**—Surgical dressers are appointed every six months; physicians' clerks, clerks in the children's department, orthopaedic dressers, ophthalmic and aural dressers, gynaecological ward clerks, maternity clerks, assistant physicians' clerk, dermatological clerks, assistant surgeons' dressers, dressers in the casualty room, post-mortem clerks, laboratory assistants and dressers in the venereal clinic every three months. After graduation there are a considerable number of residential and other appointments available in the Leeds General Infirmary, Leeds Public Dispensary, Hospital for Women and Children, West Riding Mental Hospital etc. occupying periods of from six to twelve months at rates varying from £20 to £150 per annum.

**Scholarship**—The university awards annually a scholarship in the form of a free admission to the lectures and classes given in the university which are covered by the composition fee. The university also awards a scholarship on the results of the first examination of the value of £28 in the form of a free admission to the clinical teaching of the infirmary.

**Fees**—It is estimated by the authorities that the approximate cost of medical education to a student in this university is £324 plus of course the expenses of living during the five years covered by the curriculum. The composition fee for the course for the first, second and third examination and for the clinical work at the infirmary is £237. The composition and clinical fee for those who have passed the second examination is £150.

Further information can be obtained from the Academic Subdean or Clinical Subdean, School of Medicine, Leeds.

#### LIVERPOOL

THE Medical School of this city is part of the university and, owing to the enlightened liberality of several men of wealth, is exceptionally well provided with special laboratories as well as with ordinary spacious and well equipped classrooms and laboratories for the instruction of students proceeding to medical degrees, and diplomas in special and ordinary subjects. All the laboratory and other rooms are situated close to one another and intercommunicate, together forming large blocks of buildings. The work of students throughout all stages of their career is arranged upon very satisfactory lines, and the teaching hospitals of which an account is given overleaf, have amalgamated to form the clinical school of the university.

**Appointments.** The nature of the appointments open to past and other students at this school will be gathered from the account which follows of the hospitals forming its clinical department.

**Scholarships.**—The awards made each year to successful students total over £1,500. They include the following: Two Holt Fellowships, one in Pathology, the other in Physiology; a Robert Gee Fellowship in Anatomy; two John Rankin Fellowships in Anatomy; a John W. Garrett International Fellowship in Bacteriology; a Johnston Colonial Fellowship in Biochemistry; an Ethel Boyce Fellowship in Gynaecology; and a Thelwall Thomas Fellowship in Surgical Pathology; one Lady Jones Fellowship in Orthopaedic Surgery (value of fellowships, one at £200, three at £150, two at £120, four at £100); a University Scholarship of £50 awarded on the results of the Final M.B. (Part A) Examinations; a Scholarship in Mechanical Dentistry of £20; two Lyon Jones Scholarships of the annual value of £21 each for two years, one for the junior and the other for the senior students; the Derby Exhibition of £15; the Clinical School Exhibition of £15; the Owen T. Williams Prize, the Tor Gold Medal in Anatomy; John Rankin Exhibition in Practical Anatomy, £25; the George Holt Medal in Physiology; the Kankhake Medal in Pathology; Mitchell Banks Medal in Anatomy; the Robert Gee Prize of £5 5s in Children's Diseases; Mary Buell Davies Memorial Scholarship (women), £60 per annum for four years; Robert Gee Entrance Scholarship (men), value of £40 per annum for four years; Dental Operating Prizes (four); Orthodontic Prizes (two); Samuels Memorial Scholarships, three at £20 each; one Thomas H. Bickerton Prize in Anatomy; Dr N. E. Robert Prize in Zymoic Diseases; Ash's Prize in Dental Surgery, value £2 2s; Gilmour Medal; and other entrance scholarships. In addition, a number of gold and silver medals have recently been instituted in the following subjects: Pharmacology, Surgery, Forensic Medicine and Toxicology, Public Health, Medicine, Obstetrics and Gynaecology, Orthopaedic Surgery, and Laryngology and Otolaryngology.

**Fees.**—Information as to the fees for the courses of instruction provided by the schools should be sought from the Dean of the Medical Faculty.

#### The Clinical School

As many as ten hospitals have combined to form the clinical school of the university, these being: The Royal Infirmary, the David Lewis Northern Hospital, the Royal Southern Hospital, the Stanley Hospital, the Royal Liverpool Children's Hospital, the Hospital for Women (with the Summit Hospital), the Liverpool Maternity Hospital, the Peto and Peto Infirmary, St Paul's Eye Hospital, and St George's Hospital for Diseases of the Skin. Between them they provide over 1,445 beds.

#### MANCHESTER

The staff of the Medical School in this city constitutes the Medical Faculty of the Victoria University, all the arrangements for the instruction of students, both in their earlier and their later studies, being of an elaborate nature. The clinical work of the undergraduates is done chiefly in connexion with the Royal Infirmary, an institution which itself contains 668 beds, and has associated with it a large convalescent home (132 beds) and a Central Branch Hospital (54 beds). The courses in mental diseases are partly taken in the County Mental Hospitals at Prestwich and Macclesfield. Instruction in practical gynaecology and midwifery is given at the Royal Infirmary and the St Mary's Hospitals.

**Appointments.**—The following are among the appointments open to past and present students of this school in connexion with its arrangements for clinical tuition: One surgical registrar, at £150 per annum; two pathological registrars, at £100 and £50 per annum; one medical registrar, at £150 per annum; a cardiological registrar, at £150 per annum; a surgical tutor, at £30 per annum; a director of the clinical laboratory, at £400 per annum; and two assistants, at £350; three assistant medical officers and three assistant surgical officers, each at £35 per annum; assistant surgical officer, rural department, at £35 per annum; seven anesthetists, from £75 to £100 per annum each; one resident medical officer, one year, £200 per annum; ditto at the Royal Lunatic Asylum, Cheddle, one year, £300 per annum; one resident surgical officer, one year, £200 per annum; three resident medical officers for Central Branch, one at £200 and two at £100 per annum; one assistant resident surgical officer, £150 per annum; one resident medical officer at the Convalescent Hospital at Cheddle, £250 per annum; two assistant medical officers to radiological department, £150 and £105 per annum; medical officer, physio-therapeutic department, £150 per annum; assistant surgical officer, gynaecological department, £35 per annum; assistant to the dermatologist, £20

per annum; and three assistant surgical officers for Central Branch, £75 per annum, ten senior and ten junior house-surgeons and ten house-physicians, appointed during the year for periods of six months, at a salary of £50 for the first six months, and £100 for the second six months. Resident officers are appointed to the gynaecological, the eye, and the ear and throat departments every three months. Clinical clerks and surgical dressers are appointed to the various departments of the hospital every three months. Non-resident clinical assistantships for qualified medical women, tenable for six months, at an honorarium of £35.

**Entrance and other Scholarships.**—The following are among the scholarships obtainable by students of the school: Rogers and Sention Scholarships in Arts (in alternate years), £40 per annum, tenable for two years; Three Hulme Scholarships, tenable for three years of £35, one being awarded annually for proficiency in subjects of general education; Two James Gaskill Scholarships of £35, tenable for two years, one being awarded annually for proficiency in the branches of mechanics and chemistry; A Dora Muir Scholarship, £30 per annum, tenable for three years and open to the competition of women students only. This is awarded triennially; Sir J. P. Kay Shuttleworth Scholarship, £30 per annum, tenable for three years, awarded triennially, open to the competition of scholars from Sedburgh School, Giggleswick School, and Burnley Grammar School; subjects—mathematics, chemistry, and mechanics; Dreschfeld Memorial Scholarship, value £20, tenable for two years and awarded triennially on the result of the Entrance Examination; John Russell Medical Entrance Scholarship, awarded annually, value £45; Two Dunlop Junior Medical Scholarships, value £50 each, tenable for one year for candidates who have not commenced the second year of study leading to a medical qualification; subjects—zoology, botany, and chemistry; One Dunlop Senior Medical Scholarship, £50 for one year, awarded on results of second M.B. Examination; Two Entrance Scholarships in Medicine, value 160 guineas, awarded annually for proficiency in arts or science respectively; Tom Jones Exhibition in Anatomy, £25, offered annually; A Robert Platt Physiological Scholarship of £90, tenable for one year; A Leach Fellowship of £100 for original research after graduation; Graduate Prize in Medicine, £5 annually; A Graduate Research Scholarship in Medicine, value £70, tenable for one year, awarded annually for proficiency shown at Final M.B. Examination, open to Graduate Prizemen; A Dunville Surgical Prize, value £15, awarded annually at graduation; The Tom Jones Memorial Surgical Fellowship, value £105, tenable for one year, usually awarded annually; The Turner Medical Prize, value £20, awarded annually for proficiency in certain subjects of the Final M.B. Examination; The John Henry Agnew Prize of £30, awarded annually for proficiency in the Diseases of Children; The Ashby Memorial Scholarship, tenable for one year (£100), for research in the Diseases of Children; offered triennially; Sidney Renshaw Prize in Physiology, one offered annually (£15); The John Henry Agnew Fellowship in Diseases of Children, £10; The John Henry Agnew Fellowship, £10; Post Graduate Medical offered triennially; Eliza Maple Holt Post Graduate Medical Scholarship for Women, £60 for one year, offered biennially; The details and regulations of the Dickinson Scholarships—(1) for Anatomy, (2) for Pathology, (3) Research Scholarship in Surgery, and (4) Travelling Scholarship in Medicine—may be obtained from the Secretary to the Trustees. The Morrison Watson Fellowship for research in Anatomy is offered annually, value £150; also the Sheridan Delepine Fellowship in Preventive Medicine, value £300, is offered biennially. The Sam Gamble Scholarships—the trustees are prepared to award four scholarships of not less than £40 per annum, tenable for not more than four years, to women students who have passed the First M.B. Examination, the conditions can be obtained from the Registrar. The Knight Prize of £50 for original research in the psychological factors in the causation of mental disorder—open to holders of the Diploma in Psychological Medicine or medical practitioners who have been registered in the university as candidates for that diploma.

**Fees.**—The composition fee for the university course in medicine is 110 guineas, payable in four instalments of 27½ guineas, but the sum does not include the fee to cover the work required for the First M.B. Examination. This is £42, payable in one instalment. Hospital fees are additional, and usually amount to about 77 guineas.

A prospectus and further information about the school and its scholarships may be obtained from the Registrar.

**Clinical Work.**—The Royal Eye Hospital, the Hospital for Diseases of the Skin, the Manchester Northern Hospital for Women and Children, the well known Hospital for Children at Pendlebury, and St Mary's Hospitals for Women and Children, the Manchester Hospital for Diseases of the Ear, the Christie Cancer Hospital, the Hospital for Consumption and Diseases of the Throat and Chest, the Ancoats Hospital, and the Salford Royal Hospital make arrangements for the instruction of students.

#### SUFFRIDGE

In this city the medical school is one of the departments of the university, being conducted and controlled by the Medical Faculty, and occupying practically the entire wing of the quadrangle of the university buildings.

looking. We ton Park. The laboratories and lecture rooms connected with the subjects of the first and second examinations—namely chemistry, physics, biology, anatomy, and physiology—are both as regards structural arrangement and scientific equipment on the most modern and complete line.

For students of pathology and bacteriology there are laboratories replete with everything necessary for the most advanced work and a large pathological museum which is open daily. In addition there is a large library and reading room. There are a number of recreation athletic and other societies all under the management of an annual elected students' representative council and large and comfortable common rooms both for men and women students. There are also two student unions—one for men and one for women students. In the university buildings there is a refectory open to all students of the school and a university journal is published fortnightly. The ordinary curricular work of the school is done at the Royal Infirmary and Royal Hospital which have amalgamated for the purpose of clinical instruction and provide over 800 beds for medical, surgical, and special cases, including diseases of the eye.

In addition, the Royal Infirmary has special departments for the treatment of diseases of the skin and ear, with beds assigned to them, whilst at the Royal Hospital there are special out-patient departments for diseases of the throat, ear, skin, orthopaedics, and mental diseases. The medical and surgical staffs attend daily, and give clinical instruction in the wards and out-patient rooms. Clinical lectures in medicine and surgery are given weekly. Instruction in the practical administration of anaesthetics is given at either institution by the anaesthetists, and the post-mortem examinations at both institutions are in charge of the Professor of Pathology, and afford ample material for study of this subject. Students are able to attend the practice of the Jessop Hospital for Diseases of Women and the Hospital for Sick Children, while special courses on fever are given at the City Fever Hospital and on mental diseases at the South Yorkshire Mental Hospital.

**Appointments.**—The following appointments are open to all students who have passed their examinations in anatomy and physiology: (1) casualty dressership, (2) surgical dressership, (3) medical clerkships, (4) pathological clerkship, (5) ophthalmic clerkships, (6) clerk to the skin department etc. These appointments are made for three months commencing on the first day of October, January, April, and July.

**Scholarships.**—Entrance Medical Scholarship value about £170 open to both sexes. Six Edgar Allen Scholarship of £125 a year for three years may be held by students taking the degree course in medicine. Two Town Trustees' Scholarship each of the value of £50 (tenable for three years for boys or girls under the age of 19 years who have been educated in a Sheffield secondary school for a period not less than two years immediately preceding the examination). Four Town Trustees' Scholarship value £50 for boys or girls under 19 years of age educated in any school in Sheffield secondary or otherwise. Town Trustees' Fellowship value £75 tenable for one year. Mechanics' Institute Fellowship value £50 (with remission of fees) tenable for one year and renewable for a second year. The Frederick Clifford Scholarship value about £50 tenable for two years. Hays Scholarship for proficiency in anatomy and physiology. Gold and bronze medals are also awarded for proficiency in various subjects.

**Fees.**—Students in the Faculty taking their complete medical course in the university pay an inclusive composition fee of £38 for each of the five years. The composition fee for the dental courses are as follows: for BDS first and third year £75, second, fourth and fifth years £25 for LDS first and second years £75, third and fourth years £25. The fees for special courses taken separately can be ascertained by inquiry of the Dean.

## UNIVERSITY COLLEGE OF SOUTH WALES AND MONMOUTHSHIRE

### WELSH NATIONAL SCHOOL OF MEDICINE, CARLIFF

The next session opens on October 4th. The courses of instruction are open to both men and women students and qualify for the degrees in medicine and surgery of the University of Wales, and for the degrees and diplomas of other examining bodies. Hospital instruction is given at the Cardiff Royal Infirmary, at the City Lodge Hospital, and at other recognized institutions. The Cardiff Royal Infirmary, together with its auxiliary, has 489 beds and

is well equipped in all general and special departments, giving facilities for every branch of study. Medical practitioners wishing to prepare for the Diploma in Public Health or for the Tuberculous Diseases Diploma of the University of Wales can attend complete courses of instruction in the school. Profectus can be obtained on application to the Dean of the Faculty of Medicine, or to the Secretary, Welsh National School of Medicine, Newport Road, Cardiff.

## SCOTT AND

As will be gathered from the following paragraphs the facilities for acquiring a medical education in Scotland are very ample whether the student be proceeding to a university degree or to a diploma. To the descriptions of the different Scottish medical centres is now added an account of hospitals which either play an official part in the education given to students or yet unqualified or offer valuable opportunities for post-graduation work.

## GENERAL

The school is conducted by the Faculty of Medicine. This comprises thirteen chairs, from which instruction is given in all the main branches of medical science—namely, botany, zoology, physics (ordinary and pre-registration), chemistry (ordinary and pre-registration), anatomy, physiology, materia medica, pathology, bacteriology, forensic medicine, surgery, medicine, and midwifery. Courses of instruction in public health and infectious diseases, tropical medicine, medical ethics, and tuberculosis are conducted by lecturers appointed by the University Court. Special opportunities for practical instruction are afforded in the laboratories and museums attached to the departments.

Clinical instruction is obtained in the Royal Infirmary (accommodating 335 patients), the Royal Mental Hospital (800 patients), the Sick Children's Hospital (85 patients), the City Fever Hospital (350 patients), the General Dispensary, Maternity and Vaccine Institution (10,000 out-patients annually), and the Ophthalmic Institution (3,000 patients annually). Courses of practical instruction are given in diseases of children at the Sick Children's Hospital, in fevers at the City Fever Hospital, in mental diseases at the Royal Mental Hospital, in diseases of the ear, nose, and throat at the Infirmary and Dispensary, in diseases of the eye at the Infirmary and Eye Institution, in venereal diseases and diseases of the skin at the Royal Infirmary.

The degrees granted in medicine are Doctor of Medicine (M.D.), Master of Surgery (Ch.M.), Bachelor of Surgery and Bachelor of Medicine (M.B. Ch.B.). A Diploma in Public Health is conferred after examination on graduates in medicine of any university of the United Kingdom.

The degree of Ph.D. is also granted in this faculty.

Bursaries, scholarships, and fellowships to the number of fifty and of the annual value of £120 may be held by students of medicine in this university. They range from £8 to £100 per annum and are tenable in most cases for two or three years. The winter session begins on October 11th, 1927, the summer session on April 17th, 1928.

**Fees.**—An income tax fee of 12s 6d is payable for instruction within the university and the fee for the degrees of M.B. Ch.B. is 33 guineas. The total cost, including hospital fees, class and matriculation fees, and degree fees, is about £236.

## EDINBURGH

THESE are two Schools of Medicine, the School of the University and the School of Medicine of the Royal Colleges of Physicians and Surgeons of Edinburgh.

**THE UNIVERSITY SCHOOL.**—This school in addition to other resources of the university has the following means of affording practical instruction: Royal Botanic Garden, Herbarium and Museum, Zoological Laboratory and Museum of Science and Art, Physical Laboratory, Chemical Laboratories, Dissection Room, Bone Room, and Anatomical Museum, Physiological Laboratory, Medical Jurisprudence Laboratories, John Usher Institute of Public Health, Materia Medica Museum and Laboratory, Post-mortem

Department of the Royal Infirmary and University Pathological and Bacteriological Laboratory, Tutorial Classes of Practice of Physics, of Clinical Medicine, and Clinical Surgery, Surgery and Midwifery, and the practice of certain other hospitals

**Fees**—The sessional fee for chemistry, anatomy lectures, physiology, pathology, materia medica, surgery, medicine, and midwifery is £6 6s. each. Physics, botany, zoology, forensic medicine, and public health, £5 5s. Practical zoology, practical anatomy (summer), morbid anatomy, practical materia medica, mental diseases, practical pathology, clinical midwifery, and medical entomology and parasitology, £4 4s. Experimental physiology, diseases of tropical climates, practical botany, histology, operative surgery, clinical surgery (per term), clinical medicine (per term), and experimental pharmacology, £3 3s. Practical anatomy (winter), £6 10s. 6d. Practical chemistry, £4 14s. 6d. Regional anatomy, chemical physiology, surgical pathology, and infectious diseases, £1 11s. 6d. Tuberculosis, diseases of children, diseases of the eye, diseases of the larynx, ear, and nose, diseases of the skin, and venereal diseases, £2 12s. 6d. Advanced bacteriology, £7 17s. 6d. Clinical gynecology and applied anatomy, £2 2s.

**Scholarships**—There are many funds for the assistance of students by means of bursaries, scholarships, exhibitions, and money awards from the beginning to the end of their undergraduate career. In addition, there are funds which help those who have taken a first degree in medicine and surgery to continue at work as research students. The value of these awards, and the conditions attaching to them, are so varied that those interested should consult the prospectus of the school itself. No other university is in a better, even if as good, position to smooth the financial path of earnest students.

**THE SCHOOL OF MEDICINE OF THE ROYAL COLLEGES**—This school is composed of lecturers licensed by the Royal College of Physicians and the Royal College of Surgeons, and also recognized by the university through their *licentia docendi*, for the sake of convenience they lecture in separate buildings near to the Royal Infirmary, but form a single corporate body governed by a board consisting of five members elected by the Royal College of Physicians, five members elected by the Royal College of Surgeons, and five members elected by the lecturers in the school. This board, with the assistance of the standing committees of the school, supervises the whole management and especially the maintenance of the efficiency and discipline of the school. The different buildings at present utilized for the purposes of lecturing are the following: (1) Surgeons' Hall, Nicolson Street, (2) New School, Bristo Street, (3) Nicolson Square, (4) Marshall Street, and other places. The teaching is similar to that of the Scottish universities, and the students receive similar certificates at the close of each session. The courses on the special subjects not included in the curriculum of the Examining Boards are also conducted by teachers specially qualified in each branch, and have for the last quarter of a century formed a special feature of the school. The fees payable for class and other instruction, and including the sums payable on admission to the examination of the Conjoint Board for the triple qualification, amount to about £180. The Calendar, giving full information regarding classes and fees, can be obtained (price 6d.) on application to the Dean of the School, Surgeons' Hall, Edinburgh.

**WOMEN STUDENTS IN EDINBURGH**—Until the close of the summer session of 1916 women students intending to proceed to graduation in the University of Edinburgh, as well as those entering for the triple qualification of the Royal Colleges of Edinburgh and Glasgow, received their training in the Edinburgh School of Medicine for Women. Now women students study under the same conditions as men, and may obtain either the university degree or the diploma of the Royal Colleges. In the university systematic lectures are given to them by the professors in the ordinary classes, which are therefore mixed. In clinical medicine and clinical surgery, however, while the lectures are attended by mixed classes, the women students are restricted to the wards of one charge. The particular wards are changed every term, each of the physicians and surgeons to the infirmary taking the women students in rotation. With few exceptions, prizes, scholarships, bursaries, and similar distinctions are open to women under the same conditions as for men. The women students also have the same privileges as in the past have been given to the men of attending a certain proportion of the extra-mural classes taught by the lecturers of the School of Medicine of the Royal Colleges. Most of the Students' Societies are open

to women, with the exception of the University Union and the Royal Medical Society. Their place is taken by the Women Students' Union and the Women's Medical Society. There is also a Women's Athletic Club, with playing fields gifted to it by the university. The membership of the Royal College of Physicians and Fellowships of the two Royal Colleges are also open to women. Information on matters connected with women's studies may be obtained from the Lady Warden, University New Buildings, Edinburgh.

#### GLASGOW

**THE UNIVERSITY SCHOOL FOR MEN**—The whole course of study required for graduation (M.B., Ch.B.) at the University of Glasgow can be taken here. Besides ample provision for lectures there is practical and clinical work at the hospitals, and practical courses are conducted in the laboratories of the following departments: Pathology, Public Health, Pharmacology, Physiology, Surgery, Anatomy, Chemistry, Zoology, Physics, and Botany, the Botanic Garden and the Hunterian Museum (Pathology) are also open to students. Well equipped new buildings have been provided for botany, zoology, practical anatomy, and operative surgery, as well as for pathology, the very large additions made a number of years ago to the chemical laboratory render it one of the most extensive in Scotland. The classrooms and laboratories for the departments of Physics, Physiology, Pharmacology, Materia Medica, Medical Jurisprudence, and Public Health are also of recent erection, and are elaborately equipped. Four additional chairs of Medicine, Surgery, Obstetrics, and Pathology have been recently established, the professors being specially attached to the Royal Infirmary, and a number of university lectureships in Clinical Medicine, Clinical Surgery, Venereal Diseases, Laryngology, Dermatology, Otolaryngology, Tuberculosis, and the Hygienic Diet. Five other chairs have been founded at the university, in Bacteriology, Organic Chemistry, Physiological Chemistry, Applied Physics, Public Health, and Pediatrics. There are also lectureships on the Surgical and Medical Diseases of Children and on Electrical Diagnosis and Therapeutics. The university, in short, has made great and successful efforts to extend and improve the accommodation of the medical departments, to strengthen the teaching staff, and to encourage post-graduation and research work. A Diploma in Public Health is now also granted. Three very extensive general hospitals in the city afford exceptional opportunities for clinical instruction—namely, the Western Infirmary (600 beds), near the university, to which the Regius Professors are attached, the Royal Infirmary (623 beds), and the Victoria Infirmary (380 beds), while the Royal Mental Hospital, Gartnavel (500 beds), the Royal Hospital for Sick Children (275 beds), the Royal Maternity and Women's Hospital (114 beds), the Glasgow Eye Infirmary (100 beds), the Ophthalmic Institution (35 beds), the fever hospital at Belvidere (680 beds) and Ruchill (249 beds), and other institutions afford facilities for the practical study of special branches. The large general hospitals of the parish council are now also available for clinical instruction in medicine and surgery. Information regarding post-graduate study will be found at page 419.

**Bursaries**—Bursaries confined to the Medical Faculty amount in annual value to about £1,000, while bursaries in any faculty amounting to about the same annual sum, may be held by students of medicine, a number of both being open to women. Several valuable scholarships may be held by medical students who have graduated in arts.

The following bursaries are open to undergraduates of both sexes. The Gibson Bursary, annual value £36, tenable for four years. This is open to medical students who are preparing for service as medical missionaries in connexion with the Church of Scotland, and will be awarded to the eligible candidate who has gained the highest number of marks in the First Professional Examination. The Arbuthnot Bursary, annual value £40, tenable for three years, is awarded by the Senate, on the recommendation of the Faculty of Medicine, to the student who is of the highest merit among the candidates as shown by their class records and their performances in the First and Second Professional Examinations. One Logan Bursary, annual value £16, tenable for four years, appointment by the Senate. Six Lorimer Bursaries (£20 and tenable for one year) are awarded to the best students in each of the following classes: botany, zoology, physics, chemistry, anatomy, physiology. The Macintosh Mental Science Bursary (£20 and tenable for one year) is awarded to the best student in the Mental Science class.

medicine of the value of £31 is awarded annually to the student of either sex attending the class of insanity who stands first in an examination in that subject the bursar to continue the practical study of the subject to the satisfaction of the Faculty of Medicine. The Gardiner Bursary, annual value £14 tenable for two years will be awarded after the autumn professional examination to the candidate who has passed in physiology at the Second Professional Examination and who has aggregate of marks in that subject and in chemistry and physics of the First Professional Examination is the highest. Of the eight James A. Paterson Bursaries two are awarded each year, they are of the value of £50 and £20 respectively and are tenable for four years, examination in mathematics and natural philosophy in June for students entering the first and second years of medical study. The following are tenable in any faculty: Four Wilson Bursaries (each £75 and tenable for four years), two Pratt Bursaries (each £20 and tenable for four years) and two Taylor Bursaries (each £10 and tenable for four years). Andrew and Bethia Stewart Bursaries (£50 each tenable for three years) candidates must have taken the M.A. degree of Glasgow. There is a special examination. Nine Glasgow Highland Society's Bursaries for students of Highland descent of the annual value of £25 and tenable for five years, two vacant each year.

The Carnegie Trust for the Universities of Scotland is empowered to pay the whole or part of the university ordinary class fees of students of Scottish birth or extraction under conditions given in the *University Calendar* and summarized at page 367 of this issue. The Dobbie Smith Gold Medal is awarded for the best essay on a prescribed subject within the science of botany. The Brunton Memorial Prize of £20 is awarded annually to the most distinguished graduate in medicine of the year, and the West of Scotland P.A.M.C. Memorial Prize to the candidate for the degrees of M.B. Ch.B. who obtains the highest aggregate marks in medicine, surgery, and midwifery in the Final Examinations. The University Commissioners have issued an ordinance to make regulations for the admission of women to certain bursaries, scholarship and fellowships. Scholarship and fellowship are offered by the Carnegie Trust in science and medicine for post-graduation study. There are also four McCunn Medical Research Scholarship (two of £200 and two of £400), for graduates in medicine of the Scottish universities, one Foulds Fellowship for Research in Medical Science of approximately £200 for three years, and one Strang Steel Scholarship value £160 for one year. There is, in addition, The Captain H. S. Rankin V.C. Memorial Prize in Pathology.

**Fees.**—The matriculation fee for each year is £2 2s. In most cases the fee for each university class is £5 5s. but in some cases it is £4 4s. For hospital attendance in the Western Infirmary students pay £12 12s. for a perpetual ticket or £1 11 6d. for a single term ticket with an additional fee of £5 5s. for each winter and £2 12 6d. for each summer clinic attendance. The fee for the same at the Royal Infirmary. The university fees for the four professional examinations total £34 13s. For the whole curriculum the fees for matriculation, class attendance, hospital attendance and professional examinations amount to about £250.

For further information apply to the Registrar, Glasgow University.

**QUEEN MARGARET COLLEGE.**—In this, the Women's Medical School of the University of Glasgow, the courses of study, degrees, regulations, fees, etc., are the same as for men. Women students have their own buildings with classrooms, reading rooms, library, etc. They are taught in some classes apart from male students, in others, together with them, but in either case have all the rights and privileges of university students. Their clinical studies are taken in the Royal Infirmary, the Western Infirmary and the Victoria Infirmary, also *inter alia* in the Royal Hospital for Sick Children, the Glasgow Lying-in Hospital, the Royal Asylum, Gartnavel Hospital, the Ophthalmic Institution, the City of Glasgow Lying-in Hospital, Belvidere and Ruchill and the Glasgow Royal Maternity and Women's Hospital.

**Scholarships.**—The Arthur Scholarship, annual value £20 tenable for three years. Open to competition by medical students of first year at the First Professional Examination on October 1928. This scholarship is restricted to women medical students.

Full information can be obtained from the Misses, Queen Margaret College, Glasgow.

**Board for Students.**—Universities houses of residence for women students, Queen Margaret Hall and Roberton Hall are situated near the College. The cost of board and residence is from 32s. 6d. to 42s. a week according to accommodation. Applications to be made to the Wardens. Another hostel near the College is South Park House, Ann Street, belonging to the Student Christian Movement and open to women students of all colleges in Glasgow. Cost of board is from 28s. to 30s. weekly. Applications to be made to the Warden.

**St. Mungo's College.**—This is the Medical School of the Royal Infirmary, which is the largest general hospital in Glasgow. The Infirmary is situated in Cathedral Square, Castle Street, and has car communication with every part

of the city. St. Mungo's College is in the Infirmary grounds, and affords full courses in all the subjects of the medical curriculum, and in all the medical subjects of the dental curriculum.

The Infirmary has (including the ophthalmic department) over 700 beds. There are special beds and wards for diseases of women of the throat, nose and ear, venereal diseases, burns, and septic cases. In the out-patient department in 1925 over 51,000 patients were treated. In addition to the large medical and surgical departments, there are departments for special diseases—namely, diseases of women of the throat and nose, of the ear, of the eye, of the skin, and of the teeth. There is also a fully equipped electrical pavilion with the latest and most improved apparatus for diagnosis and treatment.

**Appointments.**—1151 house-physicians and eleven house-surgeons who must be fully qualified, are appointed every six months and board in the hospital free of charge. Clerks and dressers are appointed by the physicians and surgeons. As many cases of acute diseases and accidents of a varied character are received, these appointments are very valuable.

**Fees.**—The average class fee is £3 3s. for summer classes and £4 4s. for winter classes. The fees for all the lectures, practical classes and hospital attendance necessary for candidates for the diplomas of the English or Scottish Colleges of Physicians and Surgeons amount to about £120. The classes are open to male and female students.

A habus of classes can be obtained on application to the Secretary to the Medical Faculty, St. Mungo's College, 55 Castle Street.

**THE ANDERSON COLLEGE OF MEDICINE.**—This school provides education in all subjects of the curriculum for both medical and dental students. The school buildings are situated in Dumbarton Road, immediately to the west of the University and Western Infirmary. The hospital practice and clinical lectures are provided in the Western or Royal Infirmary, pathology in the Western or Royal Infirmary, vaccination and dispensary practice in the Western or Royal Infirmary Dispensary. These classes are recognized by all the licensing corporations in the United Kingdom, also by the Universities of London, Durham, Glasgow, and Edinburgh (the latter two under certain conditions stated in the school Calendar). The courses (lectures and laboratory) in public health are recognized by the Scottish Licensing Board, the Universities of Oxford, Cambridge, and London, and the London and Irish Colleges.

**Fees.**—The fees for all lectures and practical work required by ordinary students, range between 2 and 5 guineas a session. In the Public Health Department the fee for a six months course is £14 14s. The Carnegie Trust pays the fees of students at Anderson College on conditions regarding which particulars may be obtained from the Secretary, Carnegie Trust Offices, Edinburgh.

A Calendar will be sent on receipt of a postcard by the Secretary to the Medical Faculty, the Anderson College of Medicine, Glasgow, W., who will forward any further information which may be desired.

The Royal Samaritan Hospital for Women, Glasgow, with 160 beds, offers facilities for clinical instruction in the diseases peculiar to women. A university lectureship—the Royal Samaritan Lectureship in Gynaecology, is associated with the hospital. The lecturer is Dr. David Stannard. Particulars may be obtained from Mr. T. Macdonald Macquarrie, M.A. Secretary, 149 St. Vincent Street, Glasgow.

#### ST. ANDREWS AND DUNDEE

The medical departments in these two teaching centres cater specially for students proceeding to the degrees of the University of St. Andrews but admit other students as well. In the former city the United College provides education in all subjects for the first two years. In Dundee University College provides for the needs of students from the beginning to the end of the five years' curriculum. Its buildings are modern, and contain fully equipped laboratories. The clinical work of the school is facilitated by various institutions. The class fees are from £6 6s. to £5 12s. 6d. for systematic classes, and from £4 14s. 6d. to £4 4s. for practical classes. The hospital ticket is £1 8s. for three months, £4 4s. a year, or perpetual, £13 6s. 8d. in one sum. The inclusive or

composition fee for the curriculum is £182. In connexion with both institutions there are bursaries and scholarships of considerable value, which are awarded after competitive examination. Information as to these can be obtained from the Secretary of the University of St. Andrews. Information regarding the clinical facilities may be obtained from the Dean of the Medical Faculty, Medical School, Dundee.

#### Clinical Work

Good opportunities for clinical work are afforded by the Dundee Royal Infirmary, the instruction given thereat being recognized for purposes of graduation by all the Scottish universities, the University of Cambridge, the University of London, the National University of Ireland, and by the Royal Colleges of England and Scotland.

### IRELAND

THERE is a choice of six schools for those pursuing their medical studies in Ireland. For clinical instruction the choice is equally satisfactory and varied, though the hospitals themselves are comparatively small. Some account of the schools follows.

#### DUBLIN

##### School of Physic

THIS school is in Trinity College, Dublin, and is carried on under the joint auspices of the University of Dublin and of the Royal College of Physicians of Ireland, the King's professors of institutes of medicine (physiology), practice of medicine, materia medica, and midwifery being appointed by the latter. Clinical instruction is given at St. Patrick Dun's Hospital, and some twelve other metropolitan hospitals and asylums are recognized by the Board of Trinity College. The courses of instruction are open to all medical students, whether they belong to the university or not.

##### The Schools of Surgery

These are schools carried on in Dublin under the supervision and control of the Council of the Royal College of Surgeons. They are formed of the College's own school combined with two famous old medical schools—Carmichael and Ledwich, they are attached to the College by charter. Its buildings contain spacious dissecting rooms, special pathological, bacteriological, public health, chemical, and pharmaceutical laboratories. Advantage can be taken of the lectures and instruction afforded by students otherwise unconnected with the College.

**Prizes.**—Among the prizes annually awarded are: The Barker Anatomical Prize (£26 5s.), the Carmichael Scholarship (£15), the Marine Scholarship (£8), the Gold Medal in Surgery, the Stoney Memorial Gold Medal in Anatomy, the H. Mienoughton Jones Gold Medal for Midwifery and Gynecology, class prizes, accompanied by silver medals, will also be given in each subject.

A prospectus can be obtained post free on application to the Registrar, Royal College of Surgeons, Dublin.

##### University College, Dublin

THIS is one of the constituent colleges of the National University of Ireland. The arrangements for the teaching of medical students from beginning to end of the curriculum are adequate. Applications for other information may be addressed to the Secretary and Bursar, University College, Dublin.

#### Clinical Work

There are numerous well arranged hospitals in and around the city, and almost all of these are recognized for teaching purposes by the Conjoint Board of Ireland, the University of Dublin, the National University of Ireland, and by like bodies elsewhere in the British Isles. Among them are the Mater Misericordiae Hospital, with 345 beds, Dr. Steevens's Hospital at Kingsbridge, with 150, Meath Hospital and County Dublin Infirmary, with 160, Meicler's Hospital, close to Trinity College, with 120, the Royal City of Dublin Hospital, with 124, the Adelaide Hospital, with 140, the Royal Victoria Eye and Ear Hospital, with 100 beds, Sir Patrick Dun's, which has a direct connexion with the School of Physic, and the combined institutions formed by the Hardwicke Fever Hospital, the Richmond Surgical Hospital, and the Whitworth Medical Hospital, with an aggregate of 220 beds.

As for the famous Dublin medical institution known as the Rotunda Hospital, this practically consists of two distinct hospitals, and is believed to be the largest combined maternity and gynecological hospital in the British Isles. It receives nearly 3,000 patients every year, and apart from ordinary out-patient work of a gynecological order, annually attends some 2,000 women at their own homes during their confinement. It possesses residential quarters for students, and, taken as a whole, offers exceptional opportunities for study both to ordinary students and to medical graduates of any nationality.

Two other important obstetric and gynecological hospitals in Dublin are the Coombe Lying-in Hospital and the National Maternity Hospital. During the year ending December 31st, 1926, the number of cases dealt with in the Coombe Lying-in Hospital were as follows: Intern maternity department, total admissions, 962; intern maternity department, total deliveries, 927; extern maternity department, total cases treated, 1,552; gynecological department, number of operations, 294. The practice of the hospital is attended by large numbers of students, post-graduates, and nurses.

At the National Maternity Hospital, Holles Street, Dublin, during the year ending March 31st, 1927, there were admitted to the maternity department 952 patients, and to the gynecological department 356, 744 cases were received in the extern obstetrical service, 848 patients were delivered in the hospital, and 664 in their homes, 323 operations were performed. During the year 67 students and post-graduates and 30 nurses availed themselves of the teaching facilities of the hospital.

#### BRISTOL

THE Medical School is part of the Faculty of Medicine of Queen's University, Belfast, and provides a complete medical curriculum for all purposes. The laboratories in connexion with the departments of bacteriology, biochemistry, biology, chemistry, physiology, pathology, anatomy, physics, and materia medica are all excellent, and there is a students' union which gives students the advantages of dining rooms, reading rooms, a library, and various recreation rooms. Women are eligible as students. Clinical instruction is given at the Royal Victoria Hospital, which was rebuilt a few years ago and has 360 beds, and the Mater Infirmary Hospital, which has 120 beds. Other hospitals open to the students of the university are the Maternity Hospital, the Ulster Hospital for Women and Children, the Hospital for Sick Children, the Ophthalmic Hospital, the Bann Ulster Eye, Ear and Throat Hospital, the Union Infirmary and Fever Hospital, the Fever Hospital, Poydsburn, the District Lunatic Asylum, the Samaritan Hospital, Foister Green Hospital for Diseases of the Chest, and the Belfast Hospital for Skin Diseases.

**Scholarships.**—(1) Eight, of the value of £40 each, are assigned as Entrance Scholarships in the Faculties of Arts, Science, and Medicine, tenable for one year, (2) fourteen Professional Scholarships, value from £15 to £40 each, (3) one Hutchinson Stewart Scholarship, £12, in mental diseases, (4) one Mackay Wilson Travelling Scholarship, £100, awarded triennially, (5) Isabella Tol Memorial Scholarship, tenable for three years, awarded triennially to a woman student, (6) Magiath Clinical Scholarship, awarded annually, value about £112, (7) two Musgrave Studentships of £200 in Physiology and Pathology. There is also a post-graduate research fund, open to all graduates of not more than three years' standing. Gold medals are awarded at the M.D. examination.

**Fees.**—The cost of the curriculum intended for students proceeding to the degrees of the Queen's University of Belfast is approximately £200. This includes examination fees and a perpetual ticket for attendance at the Royal Victoria Hospital or the Mater Infirmary Hospital, and fees for the special hospital. The course for the Conjoint Board costs about the same amount.

The Regulations of the Medical Faculty, containing full information, can be obtained on application to the Secretary, Queen's University, Belfast, price 4d.

#### UNIVERSITY COLLEGE, COVENTRY

THIS institution, formerly known as Queen's College, Coventry, is one of the constituent colleges of the National University of Ireland. It holds examinations for all the faculties of that university, in addition to continuing the work which it has hitherto performed—namely, that of providing education adapted to the needs of medical students at all stages of their career. Its first aim is to fit students for the degrees of the

National University, but students proceeding for the examinations of the Conjoint Board of England, Scotland, or Ireland, the Society of Apothecaries of London or the Apothecaries' Hall of Ireland or London University can arrange the courses of lectures which they attend and the order in which they attend them to meet the requirements of those bodies. Certificates of attendance at the college courses are also accepted by the University of Cambridge. Clinical instruction is given at the North and South Infirmarys (each 100 beds) and at the Cork Union Hospital (1200 beds). Students can also attend the Meier Hospital (120 beds) the County and City of Cork Living Hospital, the Maternity Hospital for Diseases of Women and Children the Fiver Hospital the Ophthalmic and Aural Hospital and the Linton Lunatic Asylum. The session extends from October to June.

There is a Dental School in which the degree of Bachelor of Dental Surgery of the National University of Ireland can be obtained. There is a large well equipped dental hospital in connexion with the school.

**Scholarships.**—About £3000 is available annually for scholarships in the College. Particulars as to each of them can be obtained on application to the Registrar.

**Fees.**—The fees for the lectures and hospital attendances required by the National University of Ireland course including examination fee come to about £170.

Further information can be found in the Calendar or obtained on application to the Registrar.

#### UNIVERSITY COLLEGE GALWAY

This institution is one of the constituent colleges of the National University of Ireland and includes Faculties of Art, Science, Law, Celtic, Engineering, Commerce, and Medicine. The college buildings are well lighted and well ventilated and contain dissecting rooms, anatomical theatre and laboratories for the study of physiology, chemistry, physics and other departments of medical science. For pathology and chemistry new laboratories are now provided. It has good grounds surrounding it and there are many arrangements such as a library, a college union, and an athletic union for the benefit of those belonging to the Medical Faculty, as well as for students in other departments of the college. The clinical teaching which is recognized as qualifying not only for the degrees of the National University but for those of London University and the diplomas of the various colleges in the three kingdoms is carried on at the Galway Central Hospital and the Galway Tuberculosis Hospital. The Galway Central Hospital is a general hospital, and at the two hospitals students have ample opportunities of studying zymotic and chronic diseases. The Central Hospital has a special ward for diseases of children. Every year the governing body offers about £1500 and the County Councils of Connaught offer about £3500 in scholarships. These scholarships are tenable in any faculty. Additional information regarding these scholarships can be obtained on application to the Registrar and to the Secretaries of the Connaught County Councils.

#### CLINICAL HOSPITALS IN ENGLAND

Many hospitals in Great Britain and Ireland though not connected with any medical school, open their doors either to those who have yet to be qualified, to those who are doing post-graduation work, or to both. The facilities they offer for gaining practical clinical experience are very great, and should not be overlooked. Their honorary staffs commonly make a point of giving such instruction as opportunity offers and at those situated in the larger towns there are often appointments as clinical assistants to be obtained. In addition they all have to offer at shorter or longer intervals appointments for resident medical officers, house physicians, and house-surgeons. These are usually paid offices which may be held for periods varying from six months to a year. Some of those situated in the great medical centres in the provinces, and in Scotland and Ireland have already been mentioned in speaking of the medical schools in these localities, but it should be added that there are many other provincial hospitals where admirable work is done, and at which much valuable experience

can be gained by both senior and junior students, and by those already qualified. Cases in point are the Royal Infirmary Bradford, the Royal Sussex County Hospital Brighton, the Royal United Hospital Bath, the Kent and Canterbury Hospital the Derbyshire Royal Infirmary, South Devon and East Cornwall Hospital Plymouth, the Royal Albert Hospital and Eye Infirmary Devonport, the Royal Devon and Exeter Hospital the West of England Eye Infirmary Exeter, the Gloucestershire Royal Infirmary and Eye Institution the Royal Infirmary Leicester, the County Hospital, Lincoln, the General Hospital Northampton, the Norfolk and Norwich Hospital, the General Hospital, Nottingham, the Royal Portsmouth Hospital, the Royal Berks Hospital Reading, the Royal South Hants and Southampton Hospital, the Staffordshire General Infirmary, Stafford, the North Staffordshire Infirmary at Hartsill, the Royal Hants County Hospital Winchester, the Wolverhampton and Staffordshire General Hospital the County Hospital York and the Coventry and Warwickshire Hospital.

#### London Clinical Hospitals

As for the hospitals in the metropolis so many of these take a share in the giving of clinical instruction that it is worth while to classify them.

**Children's Hospitals.**—There are at least seven of these the leader among them being the Hospital for Sick Children Great Ormond Street which has 240 beds. There are also the East London Hospital for Children Shadwell with 124 beds the Queen's Hospital for Children Bethnal Green with 134 the Victoria Hospital for Children Chelsea with 104 the Belgrave Hospital for Children which has a considerable out-patient department but in-patient accommodation for only 40 children the Paddington Green Children's Hospital an institution of about the same size and the Evelina Hospital for Sick Children Southwark Bridge Road with 75 beds. The largest and the oldest of the hospitals for both women and children is the Royal Waterloo Hospital for Children and Women Waterloo Road S.E.1.

**Hospitals for Women.**—Queen Charlotte's Maternity Hospital Marylebone Road with 70 beds and a residential college for students and practitioners specializes in the teaching of midwifery. The Samaritan Hospital for Women Marylebone Road admits qualified practitioners as clinical assistants to both the in-patient and out-patient departments; demonstrations are given daily in both departments; the fees—payable in advance—being £3 3s. for three months. Full particulars may be obtained from the secretary. In addition may be mentioned the Hospital for Women Solio Square whose teaching is confined to post-graduates in limited numbers, the Chelsea Hospital for Women Arthur Street Chelsea and the Elizabeth Garrett Anderson Hospital for Women in Euston Road the latter being in the nature of a general hospital so far as concerns the class of case treated.

**Eye Hospitals.**—The largest of these is the Royal London Ophthalmic Hospital (Moorgate) City Road. At this hospital two complete courses of instruction are given during the year—October to February and March to July—comprising the following subjects: anatomy, physiology and optics, ophthalmic medicine and surgery—(1) external diseases (2) motor anomalies and squint (3) ophthalmoscopic conditions (weekly classes) (4) pathology practical refraction classes methods of examination (practical) operative surgery practical pathology practical bacteriology x-ray and radiotherapy clinical lectures discussion classes. A fee of 24 guineas entitles the holder to one full five months' course (with the exception of practical pathology and practical bacteriology) together with a permanent ticket for the practice of the hospital. Fee for the practice of the hospital (permanent) £5 5s. for three or six months £3 3s. for two months £2 2s. for one month £1 1s. Gentlemen are eligible under certain conditions for the posts of chief clinical assistant, clinical assistant and junior assistant. Clinical work takes place every morning at 9 o'clock, and operations at 10. An additional special course in the preliminary subject (namely anatomy, physiology and optics) for the D.O.M.S. and other examinations in ophthalmology will be held immediately preceding the date of the examination. The fees for this course will be 12 guineas or £5 5s. for any subject separately. Further particulars may be obtained from the Dean of the Medical School. Other eye hospitals are the Royal Westminster Ophthalmic Hospital near Charing Cross, the Royal Eye Hospital Southwark and the Central London Ophthalmic Hospital Judd Street W.C.1 each with about 50 beds.

**Fever Hospitals.**—The Metropolitan Asylums Board has under its control a good many institutions in and around London for the treatment of the more serious zymotic disorders; it makes special arrangements for the instruction of students in this subject and grants certificates at the end of the courses. Detailed information should be sought from the Clerk to the Board Victoria Embankment E.C.4.

**Chest Hospital.**—The largest of these is the Brompton Hospital for Consumption which has 333 beds and a large sanatorium at Framley with 150 beds. There is also the City of London Hospital for Diseases of the Chest Victoria Park with 125 beds and the Pora Hospital for Diseases of the Chest City Road, now amalgamated with the Pora Northern Hospital Holloway Road.

*Neck, Throat, and Ear Hospitals*—The institutions which confine their work to disorders of the throat, nose and ear all make special arrangements for the benefit of senior and post graduate students. They are the Metropolitan Ear, Nose, and Throat Hospital, Fitzroy Square; the Royal Ear Hospital, Dean Street; the Central London Throat, Nose and Ear Hospital, Gray's Inn Road; and the Hospital for Diseases of the Throat, Golden Square—the last which possesses 75 beds, being the largest of the four institutions.

*Miscellaneous Special Hospitals*—Among these are the Bethlem Royal Hospital, St. George's Fields, S.E.1, which (like the Maudsley Hospital) confines its work to the treatment of mental diseases and includes a department for nervous and early mental disorders; West End Hospital for Nervous Diseases, 13, Welbeck Street, W.1; St. Peter's Hospital for Stone and Urinary Diseases, Henrietta Street, Covent Garden; St. Mark's Hospital, City Road, which devotes itself to the treatment of diseases of the rectum, including cancer and fistula; the National Hospital for Diseases of the Heart in Westmoreland Street, W.1; St. John's Hospital for Diseases of the Skin in Leicester Square; the Hospital for Diseases of the Skin, Stamford Street, Blackfriars; and the National Hospital, Queen Square, W.C.1, an institution possessing 200 beds and a world wide reputation.

Detailed information as to the teaching arrangements of all these institutions may be obtained on application to their secretaries.

## WOMEN IN MEDICINE

The regulations of the General Medical Council and of the various universities and colleges set out in previous sections apply to women as to men.

### Examinations

Women are admitted to all the medical examinations of the following qualifying bodies: the Royal College of Physicians, London; the Royal College of Surgeons of England; the Society of Apothecaries of London; the Conjoint Boards in Scotland and in Ireland; and all the universities of Great Britain and Ireland. The Royal College of Physicians now allows women to be eligible for election as Fellows.

### Medical Education

The London (Royal Free Hospital) School of Medicine for Women, which is one of the constituent schools of the Medical Faculty of the University of London, is the sole school for medical education which admits women only. All the resident appointments at the Royal Free Hospital, of which there are twenty-seven yearly, are held by women. Arrangements are made for students of the school to obtain clinical instruction at the National Hospital for Nervous Diseases, the Royal London Ophthalmic Hospital (Moorgate), the Elizabeth Garrett Anderson Hospital, the South London Hospital for Women, and the Cancer Hospital. During the past year a large children's department under a physician for diseases of children has been added to the hospital. There is also a special orthopaedic department. Further particulars with regard to the London School of Medicine for Women will be found on page 407.

Women are also admitted to the following men's schools in London: University College Hospital (a limited number only), King's College Hospital, Charing Cross Hospital, and the Westminster Hospital. Further particulars about these schools will be found in the article on London Medical Schools at page 402 et seq. The medical schools of Birmingham, Bristol, Cardiff, Leeds, Liverpool, Manchester, Newcastle, and Sheffield admit women. In Scotland, the medical schools of Aberdeen, St. Andrews, Edinburgh, and Glasgow admit women, although they do not in every case afford them equal facilities with men. The Irish universities and colleges are open to women.

### Openings for Medical Women

The London School of Medicine for Women celebrated its jubilee in October 1924. During the fifty-three years of its existence over 1,500 women have graduated from this school. At the present time most of them are engaged in active medical work. Unemployment is apparent in all professions and applies to both sexes; it is asserted that in legal women are rather more fortunate in this respect than women in other professions. In private practice they do increasingly well and are reported to be in greater demand as locumtenents for medical men and women.

The Public Health Service and especially its department of Maternity and Child Welfare, provides openings for women. In addition nearly all the voluntary welfare centres in the country are officiated by medical women. The rapid growth in recent years of maternity and child welfare centres has given women, to whom such work is peculiarly suited, an opportunity of participating in this important branch of preventive medicine. Under the Board of Education there are appointments for women as medical advisers and school medical inspectors. The London County Council has medical women as lecturers and examiners on the care of children, home nursing, health, and first aid. Many of the venereal disease clinics have at least one medical woman on the staff. A certain number of appointments as tuberculosis officers are held by women. Appointments are held by women as residents in general hospitals, hospitals for women and children, sanatoriums, infirmaries, fever hospitals, and asylums.

Particulars of the Colonial appointments which may be held by women in British West Africa and the Malay States can be obtained from the Medical Branch of the Colonial Office. Information regarding the women's medical service for India may be obtained from the honorary secretary, United Kingdom Branch of the Countess of Dufferin's Fund, c/o General J. B. Smith, India Office, Whitehall, S.W.1. Missionary societies also offer employment to medical women. Further particulars can, we understand, be obtained from Dr. Webb Anderson, Medical Missionary Association, 49, Highbury Park, London, N.5.

### Equal Pay for Equal Work

The British Medical Association was the first of all professional organizations to lay down the principle that no distinction should be made on the ground of sex as regards the emoluments to women members of the profession. Attempts are continually being made by public authorities to obtain the services of women doctors at lower salaries than those paid to men, and the Association looks to all medical women to help it in resisting such attacks upon the solidarity of the profession. In its constant efforts to maintain this principle the Association works in close co-operation with the Medical Women's Federation (9, Clifford Street, New Bond Street, W.1). In defence of the principle the British Medical Association has at various times fought—usually with success—Government departments and local authorities of all kinds. Where the authorities concerned have declined to recognize the justice of the claim that equal pay should be given for equal work the machinery, local and central, of the Association has been put into operation, and as a result the authority has generally been fit to drop the proposed distinction between men and women practitioners or given up the attempt to fill the post. It is hardly necessary to add that the British Medical Association can only be successful in carrying out this policy if it receives the loyal support of all medical women.

## DEGREES FOR PRACTITIONERS

At one time it was almost the universal custom for medical students educated in London and aiming at general practice not to seek a university degree, and as that custom still prevails to a considerable extent a large proportion of medical men in England possess diplomas or licences to practise but not degrees in medicine. This is a fact which they sometimes find reason to regret, and to such practitioners the following paragraphs may be of interest. It should be noted that the M.D. Brux. diploma, if obtained subsequently to June, 1886, is not registrable, and that the University of Brussels no longer holds special examinations for foreign medical practitioners.

### UNIVERSITY OF DURHAM

The degree of M.D. is granted by the University of Durham to registered practitioners of not less than five years' standing who have been qualified and in practice at that period, upon the following conditions, without fee:—The candidate must be 40 years of age and must produce a certificate of moral character from three registered medical practitioners. Should he not have practised

in examination in arts previous to the professional examination in virtue of which his name was placed on the Register, he is examined in classics and mathematics, if otherwise, he is required to translate into English passages from any one of the following Latin authors: Cæsar, De Bello Gallico (first three books), Virgil, *Æneid* (first three books), or Celsus (first three books). Natives of India or the British Colonies are placed on the same footing as natives of Great Britain. Natives of India must produce evidence from an Indian university that they have passed within one year an examination in Latin.

**Professional Examination.**—The candidate must pass an examination in the following subjects: (i) Principles and practice of medicine, including psychological medicine, hygiene, and therapeutics, (ii) principles and practice of surgery, (iii) midwifery and diseases of women and children, (iv) pathology, medical and surgical, (v) anatomy, medical and surgical, (vi) medical jurisprudence and toxicology. Candidates are examined by means of written papers, clinically, and *vis a voce* at the College of Medicine, Northumberland Road, Newcastle, and in the Royal Victoria Infirmary. The classical part of the examination may be taken separately from the professional on payment of a portion (£10 10s.) of the full fee.

The examinations are held twice a year, in June and December. Notice, accompanied by the fee and certificates, must be sent to the Registrar of the University of Durham College of Medicine, Newcastle-on-Tyne, at least twenty-eight days before the commencement of the examination.

**Fees.**—The fee is 50 guineas which includes the degree fee; a candidate fails to pass 20 guineas are retained but if he present himself again 40 guineas only are required.

#### UNIVERSITY OF EDINBURGH

At a meeting of the Edinburgh University Court on March 21st 1927, a regulation for the examination for the degree of M.D. was adopted on the recommendation of the Senatus. The object of this new regulation is to provide an examination suitable for testing either persons who have been in general practice or those who have been occupying their time in research work. The examination is to consist of two parts—a major and minor. For those who have been doing clinical work the major part will be an examination in clinical medicine, including a practical and oral examination and a written paper in medicine and therapeutics. While the minor part will be a special branch of medical science or practice professed by the candidate and to be approved by the Faculty of Medicine. For those who have been doing research work or engaged in some special employment, the major part will consist of a special branch of medical science or practice professed by the candidate and approved by the Faculty, and the examination will include a practical and oral examination and a written paper in the subject proposed. The minor part for these persons will be an examination in clinical medicine.

#### THE SWISS UNIVERSITIES

The Universities of Lausanne and Berne have arrangements which permit British practitioners to proceed to the M.D. degree. At Lausanne which has a large Medical Faculty, the British practitioner has to produce (1) a certificate of matriculation in a British university or of having passed a preliminary examination recognized by the General Medical Council for the purposes of registration as a medical student, (2) a certificate of a degree or diploma qualifying for practice in the United Kingdom and the certificate of registration as a medical practitioner in the United Kingdom. He must then undergo a *vis a voce* examination in any three subjects of the final medical examination which he may select. Next he must present a thesis for the doctorate prepared and completed in one of the Lausanne clinics under the direction of one of the professors of the Faculty of Medicine. Residence for a student (October to March or April to July) is obligatory. The fees are on matriculation 20 francs, on inscription for the *vis a voce* examination 50 francs, on presentation of the thesis 200 francs, for diploma and graduation 25 francs, for courses of lectures and laboratory instruction 80 francs, the printing of the thesis costs from £7 to £12. Applications for admission should be made to the Dean of the Medical

Faculty, Ecole de Médecine, Place de l'Ours, Lausanne. An official publication (*Guide de l'Étudiant*) is issued in October and April, and may be obtained (price 50 centimes) from M. F. Heschel Dufer 3, Rue Centrale, Lausanne. The university degree of M.D. (Lausanne or Berne) alone does not confer the right to practice in Switzerland, for which the possession of the State or Federal Diploma is necessary. Neither degree is registrable in this country. Dr. C. A. H. Franklin (56, Southborough Road, Bickley, Kent), honorary secretary of the Franco Medical Graduates, will supply further information.

## POST-GRADUATION STUDY

THERE has not hitherto been in this country any large and fully organized centre for post-graduate instruction; the situation has been materially changed by the statement made by the Minister of Health in the House of Commons on June 25th. Some six years ago the then Minister of Health (Dr. Christopher Addison) appointed a committee under the chairmanship of the Earl of Athlone, to investigate the needs of medical practitioners for further educational facilities in London. That committee made two recommendations: the first was that such a school attached to a hospital centrally situated in London should be devoted solely to post-graduate medical education, and that it should be a school of the University. The second recommendation was that an institute or school of State medicine should be established in London and should receive substantial financial assistance from the Treasury. The second recommendation was quickly realized, and the School of Hygiene and Tropical Medicine was brought into existence, with a Treasury guarantee for its maintenance. The Rockefeller Foundation made generous contributions for the erection of a fine building, the situation of which is now rising in the University quarter of London. Dr. Andrew Balfour is the director, and appointments to the professorial staff are being made. Further particulars about this school will be found at page 420. No steps, however, were taken to carry out the first recommendation of the committee until about a couple of years ago, when the Minister of Health appointed a departmental committee to draw up a practicable scheme of post-graduate medical education centred in London. This committee has not yet reported, but in his statement to the House of Commons Mr. Neville Chamberlain made it clear that in his own mind it was practically settled that the school should be organized in connexion with the West London Hospital at Hammermith where a post-graduate college has existed on a comparatively small scale for a number of years. The new scheme contemplates a hospital containing about 400 beds, with the necessary lecture rooms and laboratories.

London already possesses several institutions which seek to provide for the wants of graduates who desire refresher classes, instruction and experience in special subjects, or, being in a service have to prepare themselves for examinations to obtain promotion. In addition many of the undergraduate schools will give facilities for attending classes and demonstrations, but they are for the most part utilized only by their own old students. It is generally agreed, however, that instruction for post-graduates cannot conveniently be provided on any large scale in an institution primarily established for the teaching of undergraduates.

At some hospitals in London—and this applies in particular to the special hospitals—it is possible to obtain clinical assistance. Such appointments are peculiarly at the more famous institutions are eagerly sought after, and those whose ambitions lie that way commonly find it advisable to seek an association with the hospital by becoming a regular student as is often possible.

The Fellowship of Medicine founded in 1913, and amalgamated with the Post-graduate Medical Association in 1919, has an office generously placed at its disposal in the Royal Society of Medicine (1 Wimpole Street, W. 1). Courses of instruction at various hospitals scattered through London are organized and a list of hospitals which welcome post-graduates, together with the names of

the teachers, is kept. Permanent schools for those who desire to revise or increase their medical knowledge exist in the West London Post-Graduate College and the North-East London Post-Graduate College. In the provinces the Universities of Oxford, Birmingham, Bristol, Manchester, and Sheffield have organized courses. At Manchester it is hoped to start a central scheme of training, taking the form perhaps, of a definite post-graduate school. In Scotland considerable progress has been made. Edinburgh receives graduates from many schools in the Dominion, as well as in this country. At Glasgow teaching is provided under three schemes: a general course of four weeks in August and September, special courses and clinical assistantships for periods of three months. In the University of Aberdeen the Faculty of Medicine has approved a three months' course from April to June, and in relation with the University of St. Andrews courses are given by the staff of the James Mackenzie Institute for Clinical Research.

#### FELLOWSHIP OF MEDICINE AND POST-GRADUATE MEDICAL ASSOCIATION

The Fellowship of Medicine has arranged regular courses in general medicine and surgery, including special departments, each lasting two weeks, the fee for each course is 3 to 5 guineas. Courses in diseases of chest, children, heart, nervous system, throat, nose and ear, dermatology, electrotherapy, gynaecology, proctology, psychological medicine, tropical medicine, urology and venereal diseases are given from time to time at the special hospitals in association with the Fellowship of Medicine. The Fellowship Programme contains a diary of the arrangements available for post-graduates in various general and special hospitals in London. Practical courses in obstetrics and child welfare are arranged throughout the year, the duration of each course is one week. The programme for the immediate future includes a two weeks' course in general medicine and surgery, from September 19th to October 1st, at the Westminster Hospital. There will also be special courses in diseases of children at the Queen's Hospital from September 12 to 24th in ophthalmology at the Royal Westminster Ophthalmic Hospital from September 12th to October 1st, in psychological medicine at the Bethlem Royal Hospital from September 6th to October 1st, and a course in orthopaedics at the Royal National Orthopaedic Hospital from September 19th to October 1st. The offices of the Fellowship are, in kind permission of the Royal Society of Medicine, at No. 1, Wimpole Street, W.1 (telephone, MAYfair 2235). The secretary is in attendance daily from 10 a.m. to 5 p.m., excepting Saturday. The annual subscription for membership of the Fellowship of Medicine and Post-Graduate Medical Association has been fixed at a minimum of 10s.

The Fellowship arranges during the autumn and winter sessions a series of lectures. Special clinical demonstrations in medicine, surgery, and ophthalmology are arranged also weekly from October onwards. Syllabuses will be sent regularly on application.

#### WEST LONDON POST-GRADUATE COLLEGE

The work of this institution is carried on at the West London Hospital, the first in London to devote its clinical material solely to the instruction of qualified medical men. The college started in 1895, it is provided with lecture, reading, writing and class rooms, and accommodation of all sorts for the convenience of post-graduate students. The work of the college is eminently suitable for men in general practice and officers in the services who wish to revise their general clinical knowledge.

As for ward work the students accompany the senior staff on their visits to the wards at 2.30 p.m. daily, and also go round with the resident medical officers in the morning. Out-patient work begins at 2 p.m. This department is large and affords ample facilities for post-graduates to see and examine patients. There are the usual special departments. Post-graduates are appointed to act as clinical assistants for three or six months, no charge being made. Special practical classes are held in medicine, general practical surgery, gastro-intestinal surgery, medical and surgical diseases of children, analysis of blood and urine, cystoscopy, venereal diseases, tropical diseases, retinoscopy,

ophthalmic operative surgery, and, when material is available, in operative surgery. The size of the classes is limited. A special clinic for the treatment of venereal diseases (male and female) is held every evening (Saturdays included) at 5.30. Graduates are admitted to the work of the clinic free, and certificates of satisfactory attendance and work are given.

Operations take place at 2 p.m. daily, the surgeons often availing themselves of the assistance of the graduates, and in any case making arrangements so that they can readily see what is going on. The anaesthetists give instruction in the administration of anaesthetics, including spinal analgesia, on the operating days, students being allowed to administer them under supervision, while special classes are held in each session. The pathological laboratory is in charge of a pathologist who attends every day.

Demonstrations are ordinarily given in the morning by the assistant physicians and surgeons, and by the medical and surgical registrars.

*Fees*—Hospital practice, including all ordinary demonstrations and lectures, £1 11s. 6d. for one week, £4 4s. for one month, £7 7s. for two months, £9 9s. for three months, £15 15s. for six months, £23 12s. 6d. for one year, and £45 for a life ticket. Instruction in the administration of anaesthetics is given at the rate of £3 3s. a month.

The certificates of the school are recognized by the Admiralty, the War Office, the Colonial Office, the India Office, and the University of London (for higher degrees). A prospectus can be obtained on application to the Dean.

#### NORTH-EAST LONDON POST-GRADUATE COLLEGE

The headquarters of this post-graduate school are situated at the Prince of Wales's General Hospital, Tottenham N. 15, in the midst of this densely populated North London district. It contains 200 beds, and is within a few minutes' walk of South Tottenham station, on the London, Midland, and Scottish Railway, and Seven Sisters and Tottenham Hale stations, on the London and North-Eastern Railway. It is readily accessible by electric tram from Finsbury Park and Highbury, and from Dalston, Edmonton, and other parts of North London.

The college is in association with the Fellowship of Medicine and Post-Graduate Medical Association and is recognized by the Admiralty and India Office for the purpose of study leave, and by the University of London as a place for advanced study for the M.D. and M.S. degrees, the course of practical teaching of bacteriology is approved by the University of Cambridge for its Diploma in Public Health, and there are ample arrangements for the convenience of men who are thus working, or who, being in active practice, are desirous of getting themselves into touch with modern methods. The hospital is a whole affords excellent facilities for qualified medical practitioners who wish to take part for a time in the work of an active general hospital, or to obtain special instruction in the several branches of medicine and surgery, since it is open to them to study diseases of the eye, ear, throat, nose, skin, fevers, children's diseases, psychological medicine, dental surgery, radiography, the application of electricity in disease, and the administration of anaesthetics. Throughout the sessions into which the year's work is divided, clinics, lectures, and demonstrations are given by members of the teaching staff. Operations are performed every afternoon of the week except Saturday. Special vacation or intensive courses are held at intervals throughout the year, each lasting two weeks, clinical instruction being arranged for each hour of each day.

*Fees*—Two guineas for a three months' course of study in any one department which may be begun at any time, a fee of 5 guineas admits to the whole practice of the hospital for a similar term (one month 2 guineas, and one year 10 guineas) and a perpetual ticket for the practice of the hospital may be obtained for 15 guineas.

The winter session will be opened about the middle of October as regards clinical lectures, but the clinical work of the hospital is carried on continuously.

Additional information can be obtained from the Dean of the Post-Graduate College, at the hospital.

#### MANCHESTER POST-GRADUATE COURSES

The Faculty of Medicine of the University of Manchester has arranged courses in preparation for the diplomas in psychological medicine, in public health, bacteriology, and

**MANCHESTER.** *State medicine.* There are classes also for technicians in factory and school hygiene and in venereal diseases. The Faculty of Medicine has also instituted courses to meet the requirements of graduates desiring to refresh their knowledge or to pursue further their studies in various special branches. The arrangements are in the hands of a committee consisting of certain members of the faculty of representatives of hospitals and of the medical officer of health for Manchester. Full particulars can be obtained from the Dean of the Medical School the University Manchester. A whole-time intensive course in general medicine and surgery will begin on September 12th, and continue until September 30th. An intensive course in obstetrics and gynaecology will be given from October 1st to October 8th and an advanced course in diseases of the digestive system from October 10th to December 16th. Part-time courses in certain subjects have also been arranged including tuberculosis and diseases of the ear, nose, and throat. A limited number of clinical assistantships are offered in the medical, surgical and special departments of the Manchester Royal Infirmary, the Ancoats Hospital and certain special hospitals for one, two, or three months, or longer.

#### COURSES FOR MEDICAL GRADUATES AT BRISTOL

The University of Bristol provides courses of post-graduate study for practitioners. Details of its course at the Royal Infirmary and General Hospital are announced locally. In addition, practitioners may become clinical assistants in medicine, surgery, or special subjects for periods of a month or more.

The university also holds courses of demonstrations in outlying centres in the West of England. Resident practitioners form themselves into a committee and consider the type and extent of demonstrations required. The university furnishes the lecturers and makes all the necessary arrangements. All inquiries should be addressed to the Director of Post-Graduate Studies, Pathological Department, Bristol University.

**Daily Post-Graduate Study.**—For those who are able to devote several hours each day to hospital practice the university offers special facilities for post-graduate work. Qualified medical practitioners may be appointed as clinical assistants for a period of one or more months. They may act as assistants, if times permit in more than one department and in any of the hospitals during their period of study. They will be entitled to the use of the clinical laboratories and medical library, and have the right to attend in all departments including operations, post-graduate and ordinary clinical demonstrations and post-mortem examinations.

**Post-Graduate Clinical Work.**—Demonstration courses with weekly lectures are held during May, June and July. All inquiries and applications for admission should be addressed to the Director of Post-Graduate Studies (Clinical Section), Pathological Department, University of Bristol, who can be seen on any day by appointment at the Pathological Department.

Further information as to scholarship, curricula and fees can be obtained from the Dean of the Faculty of Medicine or the Registrar of the University, Bristol.

#### NEWCASTLE-ON-TYNE

For the year 1927-28 the following post-graduate courses have been arranged by the College of Medicine, Newcastle-on-Tyne (University of Durham):

1. General courses in clinical medicine, surgery and pathology at the Royal Victoria Infirmary meeting once weekly for ten weeks. One course will be held from October to December and one from April to June.

2. Special courses of clinical instruction meeting once weekly for ten weeks in the following subjects: Gynaecology, diseases of the ear, diseases of the throat, nose and ear, diseases of the kin, venereal diseases, neurology.

Special course in midwifery will be held at the Princess Mary Maternity Hospital.

3. An intensive course of fourteen days duration in the early part of the Summer Vacation 1928.

4. In addition to the regular post-graduate courses practitioners may attend the ordinary medical and surgical practice of the Royal Victoria Infirmary for specified periods.

#### FINANCIAL POST GRADUATE COURSES

In connection with the University and Royal Colleges post-graduate courses are arranged every year from about the middle of July to about the middle of September, comprising: (a) a course in obstetrics and gynaecology, generally held from about the middle of July, this year a restricted course only in clinical obstetrics is being given; (b) a course on diseases of children, this year a restricted course only is being given during the period of the general courses; (c) a general practitioners' course; (d) a general surgical course. Courses (c) and (d) extended for four weeks from August 15th to September 10th. Similar courses are held each year.

The course in obstetrics and gynaecology comprises instruction in clinical midwifery and clinical gynaecology, obstetrics and gynaecological pathology, child welfare and ante-natal clinics, etc.

The course on diseases of children comprises clinical demonstrations and systematic lectures dealing with the diagnosis and treatment of the common and important diseases met with in medical practice and including the dieting of infants and children. The general practitioners' course includes lecture demonstrations, and, where possible, practical instruction on medical anatomy, medical side-room work, examination of the blood, x-ray and electrical therapy, morbid anatomy, and post-mortem examinations. Clinical instruction in medicine, surgery, gynaecology, diseases of children, diseases of the skin, and infectious diseases and special instruction in the diseases and methods of examination of the nervous, circulatory, respiratory, alimentary, and renal systems and in diseases of the ductless glands. The general surgical course includes lecture demonstrations on surgical anatomy, surgical pathology, and surgical x-ray diagnosis. Clinical instruction in surgery at the Royal Infirmary and Royal Hospital for Sick Children, clinical instruction in venereal diseases, surgical out-patients, surgical and gynaecological operations and special instruction in abdominal and genito-urinary and other branches of surgery.

A series of special lectures open to all graduates, is delivered thrice weekly on subjects of general medical and surgical interest including recent advances in treatment. Among the special courses also arranged are examination of the blood, vaccine therapy, clinical chemistry, diseases of the ear, nose and throat and venereal diseases.

Particulars regarding the courses, dates of commencing, fees, etc., may be had on application to the Honorary Secretary, Post-Graduate Courses in Medicine, University New Buildings, Edinburgh.

#### POST-GRADUATE MEDICAL TEACHING IN GLASGOW

Organized post-graduate medical teaching is available in Glasgow under the auspices of the Post-Graduate Medical Association. This association is composed of practically all the teaching institutions in Glasgow and the various teachers giving post-graduate instruction and its business is managed by a board elected periodically by them. The chairman of the board is Principal Sir Donald MacAlister, B.Sc., and the vice-chairman Sir Hector C. Cameron. During the winter months special courses in various subjects are conducted and from November till May there is a series of weekly demonstrations specially designed for local practitioners. A comprehensive scheme of clinical courses is carried out during the summer months from June till October, and arrangements have also been made whereby a limited number of graduates may become attached to wards or out-patient departments nominally as clinical assistants for definite periods throughout the year. As such they work under the direct supervision of the physician or surgeon in charge and carry out such detailed investigations as directed.

A general medical and surgical course is now held each year during the last two weeks of August and the first two weeks of September which is arranged to include most of the subjects of interest to the general practitioner. This year the course is being conducted from August 16th to September 11th. The forenoons are occupied with general medicine and surgical diagnosis and minor surgery, in the Victoria Infirmary and in the Western Infirmary.

In the afternoons special subjects are dealt with in the special hospitals, and in the special departments of the general hospitals, two subjects being considered each afternoon. On the four Saturday forenoons tuberculosis and infectious fevers are demonstrated at Rushall Fever Hospital.

Further information may be had on application to Dr. James Crislaw, Secretary, Post-Graduate Medical Association, 6, Woodside Crescent, Glasgow, C 3.

#### AUSTRALIAN AND NEW ZEALAND MEDICAL ASSOCIATION

The Australian and New Zealand Medical Association gives information and advice to medical visitors from the Commonwealth and Dominions with regard especially to attendance at special clinics, post-graduate work, and facilities for preparing for examinations such as the M.R.C.P., F.R.C.S. (England and Edinburgh) and the D.P.H., and also as to house appointments and clinical assistantships in London and the provinces. Information will also be given as to lodgings, sports, and social opportunities. All medical graduates or undergraduates born in Australia or New Zealand and resident in or visiting England are eligible to become members. The fee is one payment of 5s. Further information can be obtained from the joint honorary secretaries, Mr. E. T. C. Milligan, F.R.C.S., and Mr. Bedford Russell, F.R.C.S., 86, Harley Street, London, W 1.

## TROPICAL MEDICINE

There are large and important schools of Tropical Medicine in London and Liverpool, and several universities and other examining bodies have instituted diplomas or degrees in the subject. The Colonial Office now expects all nominees for the Colonial Medical Service to pass through one or other of the two schools mentioned before their appointments are confirmed, and commercial firms engaged in tropical enterprise commonly demand from medical applicants for employment corresponding evidence of special knowledge. Information with regard to these schools and diplomas and degrees follows.

#### DIPLOMAS AND DEGREES

**LONDON UNIVERSITY**—Tropical medicine is one of the six branches in which the M.D. degree may be obtained. The regulations relating to the curriculum and examination correspond to those applying to the other branches.

**LONDON CONJOINT BOARD**—This body grants a diploma in tropical medicine and hygiene to candidates after an examination held in the months of February and July. Candidates must present evidence of having attended, subsequently to obtaining a registrable qualification in medicine, surgery, and midwifery, (1) practical instruction in pathology, protozoology, helminthology, entomology, bacteriology, and hygiene in relation to tropical medicine, in an institution recognized for this purpose, during not less than five months, (2) the clinical practice of a hospital recognized for the study of tropical diseases during not less than five months. These conditions may be modified in the case of candidates who have had practical experience in tropical countries. The fee for admission to the examination is £9 9s. The Board also grants diplomas in public health, in psychological medicine, in ophthalmic medicine and surgery, and in laryngology and otology. Candidates must hold a medical qualification registrable in the United Kingdom, or be graduates in medicine of a recognized Indian, Colonial, or foreign university. Particulars and conditions of admission to these examinations, fees, etc., may be obtained from the Secretary of the Examining Board, Examination Hall, Queen Square, London, W C 1.

**UNIVERSITY OF LIVERPOOL**—A diploma in tropical medicine is given by this university to students who have attended the courses provided by the Liverpool School of Tropical Medicine and have passed the examination held twice a year by the university examiners. The subjects of examination are (a) tropical pathology and parasitology, (b) entomology, (c) tropical medicine, including etiology, symptoms, diagnosis and treatment of tropical diseases. Fee for the course, £21. A diploma in tropical hygiene

(D.T.H.), open to the holders of the D.T.M., has recently been established. The subjects of examination are bacteriology, chemistry (including meteorology and climatology), entomology, protozoology and helminthology, tropical sanitation (including sanitary engineering), practical sanitation. Fee for the course, £10 10s. Further information can be obtained from the Dean of the Faculty of Medicine, University of Liverpool.

**UNIVERSITY OF CAMBRIDGE**—This university grants a diploma in tropical medicine and hygiene to any person whose name has been on the *Medical Register* for not less than a year provided that he passes the examinations of the university in this subject. Candidates for Part I are examined in the same subjects as candidates for Part II for the Diploma in Public Health. Before admission to Part II, the subjects for which are medicine, surgery, and hygiene in their relation to tropical diseases, candidates must have passed Part I. An examination for Part I is held in April and for Part II in July. The fee for each part of the examination is 10 guineas. Application for further information should be made to Mr. J. L. Purvis, Public Health Chemical Laboratory, Medical School, Cambridge.

**UNIVERSITY OF EDINBURGH**—Candidates for the Diploma in Tropical Medicine and Hygiene granted by the University of Edinburgh must be graduates in medicine and surgery of that university, or hold corresponding registrable degrees or qualifications of some other licensing body. The examinations are written, oral, and practical, and are held twice a year (June and December). Candidates are required on the first occasion of presenting themselves for examination to appear for all the subjects. Those who fail to pass the entire examination within a period of twelve months after first appearance are required to reappear for all the subjects. Full particulars can be obtained from the Dean of the Faculty of Medicine, Edinburgh.

#### SCHOOLS

##### LONDON SCHOOL OF HYGIENE AND TROPICAL MEDICINE (UNIVERSITY OF LONDON)

The London School of Hygiene and Tropical Medicine is a school of the University in so far as its active departments are concerned—namely, the Department of Bacteriology and Immunology, the Department of Lepidology and Vital Statistics, and the Departments concerned with the teaching of Tropical Medicine and Hygiene. An advanced course of study for the diploma in bacteriology, intended for a limited number of post-graduate students and lasting for one academic year, will commence on October 4th, 1927, and courses of instruction (minimum period three months) in the application of statistical methods to the problems of Epidemiology and Public Health Administration will also be instituted on October 4th. The work which prior to August 1st, 1923, was carried on by the London School of Tropical Medicine continues for the present in the building occupied by the Hospital for Tropical Diseases at Endelburgh Gardens, W C 1, where the specially equipped laboratories, museum, library, and clinical facilities afford excellent opportunities to those who may be desirous of studying diseases incidental to tropical climates before entering the services or going abroad. In the wards of the Hospital for Tropical Diseases it is to be found cases such as may be met with in actual practice in the tropics. There are two courses in the year, each lasting twenty weeks, beginning October 3rd, 1927, and March 12th, 1928, respectively. The course is so arranged as to equip men for the D.T.M. and H.Camb. Clinical instruction is also provided for the second part of the D.T.M. and H.Camb. Tropical medicine is a sixth alternative subject for the M.D. of the University of London, and the school curriculum is adapted to afford facilities for candidates desirous of taking the M.D. in this subject. The course in Tropical Hygiene may be taken separately, if desired. Research studentships and scholarships are available. Further information

may be obtained from the Secretary, London School of Hygiene and Tropical Medicine, 23, 1 and Leigh Gardens, London, W C 1

#### THE UNIVERSITY OF EDINBURGH

A course of instruction for the diploma is given during the autumn term (October to December), and includes tropical hygiene, bacteriology, entomology, and parasitology, and diseases of tropical climates (systemic and clinical). The University is included in the list of institutions whose courses of instruction in tropical medicine may be taken by officers of all Colonial Medical Services on first appointment or during study leave. Full particulars can be obtained from the Dean of the Faculty of Medicine.

#### LIVERPOOL SCHOOL OF TROPICAL MEDICINE

This school is affiliated with the University of Liverpool. The University now grants diplomas in tropical medicine (D.T.M.) and in tropical hygiene (D.T.H.).

Two full courses of instruction, each lasting about eleven weeks, are given every year for the D.T.M., commencing respectively October 1st (Autumn term) and January 7th (Lent term), and two courses for the D.T.H., beginning on January 7th and April 22nd (Summer term). The D.T.H. can only be taken by those who have obtained the D.T.M. Students who do not desire to take the diploma examinations held by the University at the end of each term are given a certificate if attendance has been satisfactory.

Fees—(1) For the D.T.M. course, 20 guineas; for the D.T.H. course, 10 guineas. (2) For the diploma examinations, 5 guineas. An extra charge of one guinea is made for the use of a microscope required.

The new laboratories of the school adjoin the University and the tropical ward of the Royal Infirmary. The dimensions of the building are 162 feet in maximum length by 84 feet in width. In addition to the basement in which are accommodated the photographic department and large storage rooms, there are four floors. The ground floor has (1) lecture theatre, with accommodation for about seventy students, (2) library, (3) a spacious museum with preparation room adjoining. The first floor has twelve rooms in which are housed the Departments of Tropical Medicine and Entomology. The second floor has the main clinical laboratory, 69 feet by 58 feet, excellently lighted, and three other rooms devoted to the Department of Parasitology. The third floor has a large research laboratory and two research rooms. On the roof is an insectorium, a mosquito-proof house and other accommodation.

Since its foundation the school has dispatched to the tropics thirty-two scientific expeditions, many of the workers having been taken from among its students. The work done by the staff has been published in twenty-one special memoirs—in the *Annals of Tropical Medicine and Parasitology* issued by the school and in numerous articles in the scientific press.

The school has also two laboratories in the tropics, the Manaus Research Laboratory in Brazil and the Sir Alfred Lewis Jones Tropical Laboratory in Sierra Leone, which was opened on January 10th, 1922, and is staffed by the school. Further information may be obtained from the Honorary Dean, School of Tropical Medicine, Pembroke Place, Liverpool.

## PSYCHOLOGICAL MEDICINE

It cannot be impressed too strongly upon the medical student that a knowledge of mental disorder is just as essential as a knowledge of the other forms of disease which he will be called upon to treat in the routine of general practice. It must be understood that by the term "mental disorder" is not only meant those severe forms which are to be found in asylums, but the term also includes mental defects of all grades, nervous, difficult and backward children, the mild and often unrecognized psychoses and also the various types of psychoneurosis. Such disorders provide the general practitioner with a large proportion of his most difficult cases, and he will find a good knowledge of mental disorder invaluable in his work. Apart from general practice, the student who proposes to take up a

career in the prison service or, still more importantly, the school medical service, will find a knowledge of psychological medicine an almost essential part of his equipment.

#### Instruction

Though at the present time the instruction given to the student is far from adequate to supply the knowledge or mental disorder requisite for the needs of the general practitioner, the facilities for the study of psychological medicine in the general hospitals are now much greater than in former years. Thus many of the teaching hospitals have out-patient departments for the treatment of mental cases, and in some of these hospitals special lectures are given on psychopathology. The facilities need not be utilized by the student, however, and the compulsory part of the curriculum is confined to formal lectures and a few attendances at some mental hospital. Here the student is apt to see mainly the terminal states of mental disease, and he is also apt to gain the impression that mental disorder is necessarily related to segregation and custody. We would therefore impress upon him the importance of attending the out-patient department for mental disorders where he will be able to observe the mild and early cases such as he will hereafter meet with in general practice.

A scheme is now in actual operation at the Maudsley Hospital in which a small number of mental cases are treated in the hospital as inpatients. This is an important move from the teaching point of view because the student will gain true insight into the relation between mental disorder and medicine as a whole and he will realize that it is a form of illness to be studied with other diseases and to be treated along similar lines.

In London post-graduate courses of instruction of a comprehensive kind are given at the Maudsley Hospital and at Bethlem Hospital, and at the National Hospital, Queen Square. Courses are arranged to meet the requirements for the diploma in psychological medicine in regard to nervous diseases. Courses in mental deficiency are arranged by the University of London. There are also post-graduate courses at the Universities of Glasgow, Cambridge, Edinburgh, Birmingham, Leeds, Manchester, Durham, and elsewhere.

#### Diplomas

Those who are taking up psychiatry as a career will find it desirable to obtain a diploma in psychological medicine. Such a diploma is not at present compulsory for a permanent position on the staff of all mental hospitals, but it will probably become so in course of time, just as it is now essential to obtain the D.P.H. if a career in public health is contemplated. Psychiatry is one of the branches of medicine which candidates for the M.D. degree of the Universities of London and Edinburgh can take up and, in addition, diplomas in psychological medicine to which reference has been made can be obtained from the Universities of Cambridge, London, Edinburgh, Durham, Leeds, Manchester, Dublin and the National University of Ireland and from the Conjoint Board in England and The Medico-Psychological Association of Great Britain and Ireland also grants certificates of proficiency after examination, and encourages the study of psychiatry by the offer of prizes for original and research work.

The requirements for a diploma differ to some extent in the various universities and colleges, but the following model scheme suggested by the Medico-Psychological Association and already adopted by the Royal College of Physicians of Ireland will give an indication of the scope of the examination for a diploma.

#### Model Scheme for a Diploma in Psychological Medicine

- 1 The candidate must be already a registered medical practitioner.
- 2 The candidate must present himself for examination on the subject detailed under Part I of the curriculum (see para 3) immediately he has concluded the prescribed courses of instruction or can produce such other evidence of diligent study as the subject to be examined upon as may be demanded by Part I. He must have been by special permission at least three months prior to entering for examination on Part II of the curriculum.
- 3 The candidate must not present himself for examination on the subjects detailed under Part II of the curriculum (see para 4) until he has been a registered medical practitioner for not less than two years. He must subsequently to his qualification have been in the practice of an approved mental hospital for not less

than two years or have attended for six months at a hospital ment or general for clinical instruction in psychological medicine and subsequently held a resident appointment at an approved mental institution or mental wards of a general hospital for not less than six months. In both cases he must produce a certificate from a recognized source that he can apply his theoretical knowledge and his practical acquaintance with and is well and adequately versed in the current clinical methods of examination and treatment of nervous and mental disorders. In the case of mental deficiency the certificate should include a practical knowledge of the various intelligence tests and other methods of ascertaining the degree of mental defect. He must also produce evidence of having attended, subequently to qualification, courses of lectures, demonstrations or other evidence of diligent study of the subjects upon which he presents himself for Part II of the examination, as may be demanded.

4. Curriculum. Part I—(a) Anatomy, histology and physiology of the nervous system including the autonomic system, anatomy and physiology of the endocrine glands, chemistry and cytology of the cerebrospinal fluid. (b) Psychology, systematic and experimental. Part II—(a) Mental anatomy, histology and pathology of the systems mentioned under Part I, (a) *post mortem* and laboratory technique. (b) Neurology and clinical neurology. (c) Psychiatry (including the psychoses), clinical psychiatry and the medico-legal aspects of mental disorders and mental deficiency. In addition the candidate for Part II will need to show special knowledge of any one subject, to be selected by him from the subjects comprising Part I or Part II, or may choose to be examined in any one of the following subjects: (d) Mental deficiency and the mental disorder of childhood and adolescence, and the duties of school medical officers in relation thereto. (e) Pathology as applied to mental and nervous disease. (f) Psychopathology and psychotherapy. (g) The principles of diet, vitamins and basal metabolism and their application. (h) Eugenics and vital statistics. (i) Criminology and the jurisprudence of criminal responsibility.

5. The diploma by request may be endorsed that special knowledge has been shown in the subject selected.

6. It is suggested that any compulsory attendance at lectures or demonstrations and clinical courses should be limited to the subject detailed for Part II and that the course for Part I or Part II should not exceed eight weeks.

#### Mental Hospital Appointments

Those who take up psychiatry as a career work as medical officers of public or private mental hospitals or similar institutions. Except in the larger institutions, such as those under the control of the London County Council, where a number of the medical staff are allowed to live out if invited the medical staff are resident officers, having board lodging, etc., either in the hospital itself or a residence in the grounds. Junior assistant medical officers receive about £300 to £400 per annum and senior assistant medical officers about £500 to £700, in both cases with board lodging, laundry, etc. In addition, if married, the board, etc., is commuted for cash. As the mental hospitals are under local control the salaries vary much in different asylums. Medical superintendents, whose pay commonly ranges between £800 and £1,500 per annum, are provided with a house in the grounds of the hospital and draw various allowances.

Since the passing of the Asylum Officers' Superannuation Act of 1909 all officers and others of the established staff of a public (county or borough asylum) mental hospital may retire at the age of 55 on a pension varying from one-half to two-thirds of the value of their pay and emoluments, or one-fifth for every year served, paying as contribution 3 per cent of the value of their appointments annually. This is a favourable prospect may not appeal to junior practitioners joining the services, but will eventually prove to be a valuable asset.

#### Prospects in the Public Service

Appointments to the public mental hospitals are made by the visiting committees, and in most cases only the junior posts are open to those who have not had previous experience in psychiatry. Since the public mental hospital service is a local and except indirectly not an imperial one, the promotion tends to be slow and uncertain, and the higher positions are not always advertised and thus thrown open to competition. For this and other reasons mental hospital work has undoubtedly not been in favour with newly qualified men in years past, but the general conditions of service have tended to show a progressive improvement and will in all probability continue to do so in the future.

Both the British Medical Association and the Medical Psychological Association are working separately and together to improve present conditions of service and

have, for example, already removed the "cebracy" objection to the service. The salaries have also been considerably increased, especially in the junior rank, and contrast favourably with those which were paid before the war. During the last few years considerable progress has been made in the conditions under which the insane are treated. The asylums are developing an atmosphere approximating more closely to that of the general hospitals. As a result of these developments the mental hospital service is becoming more attractive, and now affords great opportunities for the medical graduate who proposes to specialize in psychiatry.

While routine, administrative, and clerical work bulk largely in mental hospital duties, as they do in other public medical services, there is ample material, time, and scope for purely medical work and research—difficult as the subject may be—in psychiatry as one of the branches of medicine open to young graduates. Most mental hospitals are now equipped with efficient clinical laboratories, moreover, those who wish to undertake research are afforded every opportunity of doing so in the pathological department of the Maudsley Hospital and also in various other centres in England and Scotland. A change in the law, in which power is given to local authorities to make provision for the treatment of early and acute cases of mental disorder without certification, would do much to make psychiatric work more attractive to medical men. If the alteration in the law were made hospital either in the precincts or the grounds of the county or borough mental hospitals or in adjacent towns, would be erected in the course of time, or wards in general hospitals might be utilized for the same purpose. Such changes would render appointments in mental hospitals more attractive because the work would be entirely free from the custodial aspect of mental disorder, and attention could be given by the physician to purely medical problems without undue legal restrictions.

#### MAUDSLEY HOSPITAL, DENMARK HILL

A number of courses of instruction for the Diploma in Psychological Medicine have been given at the Maudsley Hospital, the details of the last course being as follows. The course consisted of two parts. In the first part lectures on the anatomy and physiology of the nervous system were given by Dr. Goll, with practical instruction in biochemistry by Captain Mann and in anatomy by Mr. C. Gray. A course on special histology of the nervous system was given by the late Dr. Di Fano, and a course on theoretical and practical psychology by Dr. Bayne. For the second part of the course lectures on normal psychology and psychiatry were given by Dr. Molyneux, on the psychoses by Dr. Bernard Hart, on the epilepsies by Dr. Petrie, on general pathology by Dr. Goll and Mr. C. Gray, and on pathological chemistry by Captain Mann. Dr. Bond lectured on the legal relationships of insanity, Dr. Shrubsole on mental deficiency and Dr. Lister on criminal insanity. Dr. Goll and Dr. Walshe gave instruction on clinical neurology, and Mr. Foster Moore on changes as applied to psychiatry. The fee for the whole course (Part I and Part II) was 15 guineas, or for either part separately 10 guineas, for one single series of lectures in Part I the fee was 4 guineas, and in Part II 2 guineas. Inquiries as to lecture, etc., should be addressed to the Director of the Central Pathological Laboratory, Maudsley Hospital, Denmark Hill, S.E. 5.

#### BETHLEM ROYAL HOSPITAL

A course will be held at Bethlem Royal Hospital, commencing on September 12th of lectures and practical instruction for the Diploma in Psychological Medicine. It is proposed in future to give two courses each year: a autumn session of intensive character, commencing in September, and completed in early December, and a spring session, commencing in the middle of January and completed in the middle of April. Each course consists of two parts. Part A includes lectures and demonstration on the anatomy, histology and physiology of the nervous system with lectures on psychology and demonstration on experimental psychology. Part B comprises lectures and clinical demonstrations in psychology, including lectures

and demonstrations in the morbid anatomy of the nervous system a series of lectures with clinical demonstrations on different branches of psychological medicine, and lectures with clinical demonstrations, on mental deficiency. Entrants for the course who pay a composition fee of 15 guineas may, if due notice is given, attend either Part A or Part B of one course and postpone the other part until the next session. An entrant who wishes to attend one part only pays a fee of 10 guineas. An entrant who takes the complete course can attend the general clinical practice of the hospital on payment of 5 guineas for six months or 10 guineas for one year, but an entrant who does not take either part of the course and desires to attend the clinical practice of the hospital must pay a fee of 5 guineas for each three months of attendance. To enable post-graduates to obtain special experience in this branch of medicine clinical assistants are appointed from time to time. Further particulars may be obtained from the physician superintendent, Bethlehem Royal Hospital, S E 1.

#### NATIONAL HOSPITAL QUEEN SQUARE

A post-graduate course which fulfilled the requirements of the regulations for the Diploma in Psychological Medicine in regard to instruction in nervous diseases was held at the National Hospital, Queen Square, Bloomsbury W C 1 in May and June and other courses will be duly announced. Lectures on the pathology of the nervous system and various clinical lectures were delivered and demonstrations were given and out-patient clinics were held at the hospital on the afternoons of Mondays, Tuesdays, Thursdays and Fridays. An inclusive fee of 9 guineas was charged for the whole course but any part of the course could be taken separately at a special fee. A special arrangement was made for those unable to attend the whole course and for details applications should be made to the dean of the medical school. Similar courses are held three times a year—namely February, May and October. Special arrangements are made throughout the year for work in the laboratory. Fees are payable to the secretary of the hospital on entering for the course.

#### THE TWISTOCK CLINIC FOR FUNCTIONAL NERVE CASES

Courses in modern psychotropic methods for the treatment of nervous breakdowns can be obtained at the Twistock Clinic, 51 Twistock Square W C 1 and those who want to specialize in this treatment can obtain clinical assistance. The methods of the clinic comprise a full and sympathetic investigation of the patient's history, sometimes dream analysis, suggestion and mental exercises where necessary, and re-education of the patient to fit him to deal with his difficulties. The director of the clinic is Dr H. Crichton Miller, the deputy director Dr J. R. Rees and there is a children's department under the directorship of Dr W. A. Potts.

## THE PUBLIC HEALTH MEDICAL SERVICES

The central authority to secure the adoption of effective carrying out and co-ordination of measures conducive to the health of the people, and to promote research work and the proper training of persons for health services, is the Ministry of Health.

For the purpose of local public health administration the whole of England and Wales is divided into counties, county boroughs, boroughs and urban and rural sanitary districts. The Administrative Council of London, exclusive of the City of London is divided into twenty-eight metropolitan boroughs.

The public health medical services for Great Britain embrace between three and four thousand medical men and women who give whole-time services and in addition a large number who give part-time services. The medical officers appointed for these services may be either medical officers of the Ministry of Health for England or of the corresponding Boards of Health for Scotland and Wales, or

—and these form the large majority—those may be medical officers appointed by the many local public health authorities. The latter appointments include medical officers of health, tuberculosis medical officer, maternity and child welfare medical officer, venereal diseases medical officers, and school medical officers—for the education authorities must now be included as health authorities in respect to the health interests of the school child. By the larger public health authorities assistant medical officers are also appointed and these posts often serve as stepping stones to the higher offices a vacancy which are required to be advertised, occur.

#### THE MEDICAL SERVICES OF THE CENTRAL AUTHORITY

The Medical Department of the Ministry of Health for England has been organized under the control of a chief medical officer. It contains six sections with a chief medical officer at the head of each and about fifty medical officers. The sections deal with general health and epidemiology, maternity and child welfare, tuberculosis and venereal diseases, the supervision of food supplies, and sanitary administration in relation to infectious diseases. There is in addition a section concerned with insurance practitioners. Appointments to these posts are not as a rule open to public competition they are made by the Minister of Health. They are civil service appointments and come under the civil service superannuation scheme. Medical officers are also employed by the corresponding Boards of Health for Scotland and Wales.

#### MEDICAL OFFICERS OF HEALTH

The duties of the medical officer of health are to inform himself upon all influences affecting or threatening to affect injuriously the public health within his district, to advise his sanitary authority upon all matters relating to health and to perform all the duties imposed upon him by statutes, by laws and regulations. He must prepare and submit to his local authority special and annual reports and immediately inform them to the Ministry of Health of any serious outbreak of disease and subject to the instruction of his sanitary authority he shall direct or superintend the work of sanitary inspection.

By the Sanitary Officers Order 1926 no person is qualified to be hereafter appointed or reappointed as a medical officer of health of any district or combination of districts unless, in addition to the qualification prescribed by statute he is also either registered in the Medical Register as the holder of a Diploma in Public Health, Sanitary Science or State Medicine or has had not less than three years previous experience of the duties of a medical officer of health.

The Public Health (Officers) Act 1921 which was promoted by the British Medical Association provides that a whole-time medical officer of health of a county borough or urban and rural district in England and Wales a part of whose salary is contributed by the Exchequer shall not be appointed for a limited period and shall not be removed from his office except by or with the consent of the Minister of Health. A similar security of tenure also applies to the medical officers of health of county councils and of London boroughs.

Under the Sanitary Officers Order 1926 a medical officer of health who does not devote his whole time to the duties of his office but a portion of whose salary is obtained from Exchequer grant may be appointed without limit of time in which case he cannot be removed from office without the consent of the Minister. If he is appointed for a specified term say one year he continues to hold office from year to year unless the Minister consents to his removal. Where the electing body pays the whole of the salary of a medical officer of health he may be dismissed from office without reference to the Minister of Health.

A considerable number of authorities have now adopted the Local Government and Other Officers Superannuation Act 1922. Under this Act if an officer is incapacitated by ill health after ten years or more or if he has reached 65 years of age he is entitled to superannuation on the following scale: after ten years is 50 per cent of the average salary which he received during the last five years of employment, after eleven years, 11/63 and so on up

to a maximum of 40/50 after forty years or more of service. The Act, however, remains permissive, and it fails to make due allowance, in computing service for purposes of superannuation, for the more advanced age, as compared with other officers, at which the medical officer of health can enter the public service. In these two respects the position reached falls short of that for which the British Medical Association has been working for many years.

In Scotland the position is different in some respects. The central authority is the Board of Health, with a staff of medical officers for insurance work. Under the Public Health (Scotland) Act, 1897, no one can be appointed as medical officer of health for any area unless he possesses the Diploma in Public Health. No medical officer can be removed from office except with the sanction of the Board of Health. A "proper" salary must be paid, and the local authority may not bring about the resignation of the officer by indirect means, such as reducing the salary or attaching conditions to the appointment. The Act says nothing about superannuation or the age of retirement.

#### SCHOOL MEDICAL OFFICERS

School medical officers are appointed by local education authorities. Primarily their duty is to detect among the children attending the public elementary schools any physical or mental defect which may retard education, and to inform their parents of its existence. Most approved schemes of medical inspection include arrangements which facilitate the task of parents in obtaining for their children the necessary treatment, check the results of this treatment, and keep each defective child under skilled observation both at home and at school until it has passed altogether out of the education authorities' hands. Indeed, it is now the practice for the education authorities themselves to provide for certain remedial work, notably the prescription of glasses where necessary, dental treatment, the removal of adenoids and tonsils, and treatment in connexion with certain diseases of the skin. The general object of all schemes alike is to make the inspection imposed by law of benefit, not merely to the individual child, but to the community at large, by preventing the development of conditions which lead to the existence of a large proportion of inefficient citizens among the adult population. The work is so related to that of medical officers of health that, as a rule, the senior school medical officer fills both appointments, his work, when necessary, being supplemented by that of whole- or part-time assistants. A Diploma in Public Health is almost always required of those entering the school medical service.

In Scotland, while the statutory authority for the work of the school medical service is different, the effect is broadly the same.

#### TUBERCULOSIS MEDICAL OFFICERS

A tuberculosis medical officer is a whole-time officer with special training and experience in tuberculosis work and of a suitable age and attainments to command general confidence. In England and Wales such officers are appointed by county councils and county borough councils, and their duties are to carry out the work of diagnosis of tuberculosis to advise as to treatment and to take charge of the work of tuberculosis dispensaries and sanatoriums where these are in operation. The work under tuberculosis schemes is co-ordinated with the general public health work of local authorities, and so the medical officer of health is often appointed as the chief tuberculosis officer when a special tuberculosis officer is on the staff of the local authority. The arrangements in Scotland are very similar.

#### MATERNITY AND CHILD WELFARE MEDICAL OFFICERS

Any public health local authority, however small, may make arrangements for maternity and child welfare work within its area, although very generally the smaller local authorities are embraced in county council schemes. For the schemes of the smaller local authorities the services of a part-time medical officer are obtained when the medical officer of health does not himself undertake the duties, but for the larger schemes special whole-time appointments are

made. The maternity and child welfare medical officer is responsible for the work at the centres provided and for directing the home visitations, and the whole of this work is closely co-ordinated with the other branches of public health work directed by the medical officer of health.

Much of this work was commenced in different parts of the country by voluntary organizations, some of it still remains in their hands, and is only loosely linked up with the public health local authority, but the tendency is for the whole of it to be undertaken by the local authorities. A large number of women medical officers have been appointed to these posts during recent years.

#### VENEREAL DISEASES

Schemes for the diagnosis and treatment of venereal diseases are provided and administered by county councils and county borough councils. In some cases the officer is on the whole-time public health staff, and in others he is a part-time official. Special knowledge and practical experience in the treatment of venereal diseases are essential. The officer appointed for either whole-time or part-time service works at one or more clinics, and also gives instructions and assistance in the treatment of venereal diseases to general practitioners, who are allowed to attend the clinics.

#### REMUNERATION FOR SERVICES

If we are to have skilled and highly trained medical officers of public authorities it is of course essential that they should receive salaries commensurate with their attainments and bearing a reasonable relation to the amount of time and money expended in fitting them for their important and responsible duties. At present, no standard scale of remuneration for whole-time services has been adopted by public health authorities, although the British Medical Association and the Society of Medical Officers of Health—and more recently the Ministry of Health—have endeavoured to bring this about.

The present-day rate of remuneration for the whole-time services of a medical officer of health may be said to vary from £700 to £2,000 per annum, according to the dimension of the population served and the officer's experience, while the maximum salaries of the principal medical officers of departments of public health work are somewhat lower. The whole-time medical officer working under a senior medical officer in most cases receives a commencing salary of £600 per annum, with bonus in some cases.

There are good prospects of the general adoption in the near future of a recognized scale of remuneration, which will provide a minimum commencing salary of £800 for a whole-time medical officer of health, of £750 for chief medical officers of departments, and of £600 for all medical officers working under chief medical officers—when they are not resident in an institution provided by the local public health authority and when they give whole-time services.

#### THE REGULATIONS FOR THE DIPLOMA IN PUBLIC HEALTH

##### The Examination

By the Regulations or Rules of the General Medical Council, which came into force on January 1st, 1924, the examination for the D.P.H. is divided into two parts, and no candidate is allowed to sit for the final part of the examination until two years have elapsed since a respectable qualification was obtained. The object of this two years' interval is "to provide opportunity for a candidate for the Diploma or Degree in Sanitary Science, Public Health, or State Medicine, to pass from the state of pupilage to that of responsible practitioner, to give proper consideration to the obligations and duties involved in the work of the Public Health Service, and to acquire direct experience of medical work in a responsible capacity either in practice or in hospital or laboratory appointments."

The examination is both written and oral, and includes practical examination in bacteriology and chemistry (Part I) and in infectious diseases, food inspection, inspection of premises, dwellings, factories, workhouses, schools, etc. (Part II).

Any candidate from the Dominions who possesses qualifications registrable in this country is eligible as a candidate for the examination given that he has received such a course of training as that defined by the Regulations at an institution which is approved by the General Medical Council.

#### *The Curriculum for the Diploma in Public Health*

The curriculum must extend over a period of twelve months and a candidate is admitted to either part of the examination after he has completed the prescribed course of instruction in the subjects thereof. At least five months must be given to practical laboratory instruction in an institution approved by the licensing body, in the subjects

(1) Bacteriology and parasitology including entomology especially in relation to diseases of man and to those diseases transmissible to man from the lower animals (180 hours of such instruction is required).

(2) Chemistry and physics in relation to public health (90 hours of such instruction is required).

(3) Meteorology and climatology (10 hours of such instruction is required).

Therefore at least 260 hours of practical instruction extending over a period of at least five months, is demanded before a candidate is eligible for Part I of the examination.

For a candidate to become eligible for Part II of the examination he must first receive instruction in

(1) Principles of public health and sanitation (for approximately 30 hours).

(2) Epidemiology and vital statistics (approximately 20 hours).

(3) Sanitary law and administration including public medical services (approximately 20 hours).

(4) Sanitary construction and planning (approximately 10 hours).

(5) Every candidate must also have made thirty attendances, of not less than two hours in each week of a three-month period, at the clinical practice of a recognized hospital for infectious diseases, and he must have received instruction in methods of administration.

(6) Every candidate must produce evidence that he has during a period of not less than six months been engaged in acquiring a practical knowledge of the duties routine and special of public health administration under the supervision of a medical officer of health who shall certify that the candidate has received from this officer or a competent medical officer during not less than three hours on each of six working days practical instruction in these duties and the one relating to

(a) Maternity and child welfare service

(b) Health service for children of school age,

(c) Venereal diseases service,

(d) Tuberculosis service,

(e) Industrial hygiene,

(f) Inspection and control of food including meat and milk.

Certificates of having received the prescribed instruction in public health administration must be given by a medical officer of health who devotes his whole time to public health work, or by the medical officer of health of a sanitary area having a population of not less than 50,000 or in Ireland by the medical superintendent officer of health of a county or county borough having a population of not less than 50,000.

#### *TRAINING CENTRES FOR THE DIPLOMA IN PUBLIC HEALTH*

Most of the universities of Great Britain and Ireland are training centres for the Diploma in Public Health. The University of London provides an M.D. in State Medicine for its own M.B., B.S. graduates.

In London at the present time there are fewer training centres for the D.P.H. than formerly. Candidates who desire to train in London can do so at University College and the Royal Institute of Public Health, and also at the Medical Schools of St. George's and Middlesex Hospitals when a sufficient number of candidates apply for the training. It is expected that in less than two years the post-graduate teaching and training in Public Health, in London, will be provided at one centre only—the London School of Hygiene and Tropical Medicine, which is in process of erection.

The University of Manchester has a well equipped department of bacteriology and preventive medicine, where candidates preparing for the examinations of the various

universities and examining boards for the Diploma in Public Health can obtain instruction. It also prepares candidates for the Diploma in Bacteriology and in Veterinary State Medicine, granted by the University, and for its Certificates in Factory Hygiene and School Hygiene. Full particulars can be obtained from the Dean of the Medical School, the University, Manchester.

The University of Edinburgh, which grants a Diploma in Public Health, makes provision for instruction in all the subjects. Further particulars can be obtained from the Dean of the Faculty of Medicine, Edinburgh.

## THE NAVY, ARMY, AIR FORCE, AND INDIAN MEDICAL SERVICES

The Medical Departments of the Royal Navy, of the Army, and the Indian Government normally employed between them before the war some 3,000 medical men, and vacancies in the ranks of these services were filled by offering commissions for competition once or more each year. In the abnormal circumstances arising out of the war and the period following it the usual regulations for recruiting the permanent medical staff of these services were, for the most part, in abeyance, and the newly formed Royal Air Force Medical Service also has depended largely upon short-service commissions for the maintenance of its medical personnel.

Meanwhile recruitment for the Royal Naval Medical Service and for the Royal Army Medical Corps was seriously prejudiced by disadvantageous terms and conditions of service generally, and in particular by hardships inflicted under new regulations upon certain groups of senior officers. Continued representations were made by the British Medical Association but without avail, and it is only lately that its efforts on behalf of these services have begun to bear fruit in the manner indicated below. The often repeated refusal to remedy grievances imposed upon the Association the distasteful duty of issuing warnings to newly qualified practitioners, but now that the Government has changed its attitude the Association is using every endeavour to assist the Admiralty and the War Office in obtaining the candidates they need. In securing the improved terms which it has pressed upon the authorities the Association gained a very notable success.

#### *Improved Terms and Conditions*

As a result of the recommendations of the Interdepartmental Committee on the Medical Branches of the Fighting Services, before whom the British Medical Association gave evidence early last year, substantial increases in the rates and pay and remuneration, gratuities and improved conditions of recruitment for officers of the Royal Army Medical Corps were embodied in a Royal Warrant issued by the War Office on June 29th, 1926. Simultaneously the Air Ministry announced improvements in the conditions of service and emoluments of medical officers of the Royal Air Force. The Admiralty also issued an Admiralty Fleet Order prescribing improved terms and conditions of service for medical officers P.N., and the India Office followed with revised terms of special recruitment for officers of the Indian Medical Service.

The changes generally took effect from July 1st, 1926, or (in the case of naval officers) as soon afterwards as the necessary arrangements could be made.

The British Medical Association, after examination of the revised terms, is satisfied with the new rates of pay and conditions of service for the P.N.M.S., the R.A.M.C., and the R.A.F.M.S., and in fulfilment of its desire to assist in recruiting these services we publish below the full particulars of each which have been supplied at our request by the Admiralty, the War Office and the Air Ministry.

In regard to R.A.M.C. officers whose particular difficulties have engaged the special attention of the Association during recent years, the increases in the rates of pay and retiring gratuities are substantial as will be seen

if the new rates are compared with the old rates promulgated by Royal Warrant after the war. But the new rates, like the old, are subject to a 6 per cent reduction owing to the decrease in the cost of living. The increases in the pay of R.A.M.C. officers do not begin until after six years' commissioned service, but from that time onwards, especially in the rank of major, very much has been done to make the service more attractive. One of the chief grievances was the fact that a major, after three years in that rank, or fifteen years' commissioned service, got no increase of pay until he was promoted lieutenant-colonel, a promotion which might possibly not take place until he had as much as twenty-four years of service. The new Warrant gives him a steady increase of pay, not only after fifteen years' service, but also after eighteen or twenty years' service. The ranks senior to that of major also participate in very substantial concessions. The retiring gratuities of a major after three and six years' service are now perhaps so great as to induce officers to retire before they become eligible for a pension, but in that case it is hoped that they will only make room for a large influx of junior officers to carry on the duties that are now being performed by those more senior in the service. The British Medical Association held out strongly for the removal of a serious grievance in regard to the retiring pension of an officer after twenty years' service, and it pointed out that it was possible in the future for a major to have to retire on a less pension than £1 a day, which had been granted to him from time immemorial. The new Warrant relieves him of anxiety in this respect, and explicitly states that his pension cannot be reduced below that amount. Another important point should be noted—namely, the concession by which a newly qualified medical man can hold a hospital appointment for one year before entering the service, counting it as a year of service towards promotion and retirement. Previously this concession was only given after the officer had entered the service. This was one of the points that were strongly brought forward in the evidence submitted by the Association to the interdepartmental committee, and should give special satisfaction to members of the medical profession. It will be seen that both the Royal Navy and Royal Air Force Medical Services have also benefited considerably by the recommendations of the committee. A further gain has been obtained for the Royal Army Medical Corps by the grant of marriage allowance for officers serving in India, an allowance that had been withheld from the R.A.M.C. officer while conceded to officers of other branches of the service. There is still, however, considerable difficulty in getting a sufficient number of young medical officers, but there is no reason why young men recently qualified should not enter the services, the prospects in which both financially and professionally are good.

### ROYAL NAVAL MEDICAL SERVICE

An Admiralty Fleet Order, issued in July 1926, announced changes in the terms and conditions of service for naval medical officers. The improvements include an increase in the establishment of Surgeon Captains from 16 to 20, and also in the number and remuneration of specialist appointments open to medical officers. These appointments comprise specialist posts in medicine, surgery, pathology, and hygiene, and the allowance payable to holders of them has been increased from 2s 6d to 5s a day. As soon as possible courses of instruction in clinical medicine, surgery, and allied subjects are to be provided once in every four years for all officers below the rank of Surgeon Captain. Courses for those selected to hold specialist appointments will be arranged in connexion with civil hospitals in London or other teaching centres. Medical officers entering the Navy on or after July 1st 1926, will be eligible, at the discretion of the Admiralty, to have their seniority antedated up to a limit of one year if they have held previously a resident appointment in a civil hospital for not less than this period. Such an appointment must be one recognized by the Admiralty for this purpose and must not have terminated more than six months before entry into the service.

Examinations for direct entry into the Medical Service are at present in abeyance. Entries are made by means of the short-service scheme, and the regulations provide for the transfer to the permanent service of desirable short-service officers. A short-service surgeon lieutenant, after six months' service, may be considered for transfer to the permanent service and would be permitted to count his seniority from the date of entry for short service for purposes of promotion, increment of full pay, and for retired pay.

#### General Conditions

A candidate must be registered, must be under 30 years of age and must be recommended by the dean of his school. Unmarried candidates will be preferred. A candidate will be interviewed by the Medical Director General, R.N., and will undergo a physical examination. If considered eligible by the Medical Director General his name will be submitted to the Board of Admiralty and he may be appointed "surgeon lieutenant for short service." A candidate must engage for three years, with the option of continuing for a further period of twelve months if his services are still required. The rate of pay is £1 4s 10d a day or £453 4s 2d a year, with the same allowances as are payable to permanent officers of their rank. Lodging money at the rate of £80 a year is usually allowed when employed on shore, without quarters in the United Kingdom, and £56 10s a year in lieu of rations when not victualled in kind. On joining an allowance of £50 for uniform will be made. When the previous rates of pay were fixed it was decided that 20 per cent should be considered as due to the then high cost of living. The rates set out above represent a reduction of approximately 6 per cent owing to the decrease in the cost of living. The whole 20 per cent is to be regarded as variable and subject to change on July 1st, 1930, and triennially thereafter either upwards or downwards according as the cost of living rises or falls.

An officer engaged for three years is entitled to receive two months' notice of his services being no longer required. A gratuity of £8 6s 8d will be payable to officers for each completed month of service on completion of their period of service, or to any who are invalided for causes not within their own control before the completion of the prescribed period.

Surgeon lieutenants R.N. for short service intending to apply for transfer to the permanent list must have been under 28 years of age at the time of their entry into the Royal Naval Medical Service.

#### MEDICAL OFFICERS R.N.

##### Full Pay

	Current Rate per annum.
	£ s d
Surgeon Lieutenant on entry	410 12 6
After 3 years	498 16 8
(Surgeon Lieutenants usually receive promotion after 6 years' service)	
Surgeon Lieutenant Commander on promotion	599 4 2
After 3 years	675 14 2
(Surgeon Lieutenant Commanders usually receive promotion after 12 years' total service)	
Surgeon Commander on promotion	772 11 8
After 3 years	839 10 0
After 6 years	909 9 2
After 9 years	976 7 6
Surgeon Captain on promotion (promotion is by selection)	1,116 5 10
After 3 years	1,201 9 2
After 6 years	1,285 12 6
Surgeon Rear Admiral (promotion is by selection)	1,780 13 4
Medical Director General (Surgeon Vice Admiral)	2,350 0 0

The current rates set out above are payable from July 1st, 1927, and represent a deduction of 6 per cent from the standard rates. 20 per cent of the standard rate is regarded as variable as the cost of living rises or falls. The next revision will be on July 1st, 1930.

#### Gratuities on Withdrawal

The following gratuities are payable if an officer of the permanent list is permitted to retire voluntarily.

	£
After 4 years' full pay service	500
" 8 "	1,000
" 12 "	1,500
" 16 "	2,250

Surgeon lieutenants for short service, transferred to the permanent list, will only be allowed to withdraw with a gratuity after four years' full pay service from the date of such transfer.

#### Maximum Retired Pay (Approximate current rate)

	£
Surgeon Vice-Admiral	1,125
Surgeon Rear Admiral	650
Surgeon Captain	250
Surgeon Commander	200
Surgeon Lieutenant Commander and Surgeon Lieutenant	125

Full particulars and a form of declaration can be obtained from the Medical Director-General, Admiralty, Queen Anne's Chambers, Tothill Street, London, S.W. 1.

# ARMY MEDICAL SERVICE

During the last two years, and in fact since the war, candidates have practically ceased to apply for commissions in the Royal Army Medical Corps. While the cause of this must to a great extent be attributed to the war, a still more potent cause hitherto has been an accumulation of grievances of a character which led the British Medical Association to refrain from recommending the army as a career for newly qualified medical men. This attitude was not now able to abandon wholeheartedly owing to the issue of a Royal Warrant last year removing practically all the grievances from which the R.A.M.C. officers were suffering.

Entrance to the corps, either by competitive examination or by selection, as decided by the Army Council, will take place half yearly, in January and July. The examinations in medicine and surgery are entirely of a clinical and practical character, partly written and partly oral. The regulations for admission, giving full details can be obtained from the Under Secretary of State (A.M.D.), War Office Whitehall, London, S.W. 1, and should be carefully studied. A personal interview with a representative of the Director General, Army Medical Services, is readily obtainable. The rates of pay and allowances are good, the opportunities of post graduate study are generous, and the work is varied, responsible, and interesting. The gratuities after certain periods of service enable an officer should he so desire to leave the service with a capital sum large enough to go a long way towards re-establishing himself in civil life and, further, the knowledge of the world and the comradeship of his fellow officers that he has gained in the army will be of no small value to him.

New entrants are commissioned in the rank of lieutenant and the first six months of service are spent on probation during which time they undergo in addition to their military training at the Royal Army Medical Corps depot at Aldershot a probationary course at the Royal Army Medical College in London in hygiene, pathology, tropical medicine, military surgery, recruiting, the prevention and treatment of venereal disease and the elements of army administration. At the end of this course and after qualifying at the necessary examinations their commissions are confirmed and they take their places in seniority according to the total marks obtained at all examinations up to that date. Officers Training Corps service with possession of certificate A or B (medical) carry a definite value in marks in this total.

An entrant who is holding or about to hold at the time of the entrance examination a resident house appointment at an approved civil hospital may be seconded while holding such an appointment up to a maximum period of twelve months. A candidate who has held such an appointment within six months of entry may be granted an antedate up to twelve months in respect of the period the appointment was held. This antedate and antedate counts in all respects as commissioned service, except that pay will not be issued for that period.

After a total period of one year's service at home the young officer goes abroad, probably to India, for his first tour of foreign service. Here he gains his first practical experience of tropical disease and tropical hygiene and possibly his first experience of active service on the frontiers of India. His tour abroad lasts five years with probably six months leave home during that time. On returning home the R.A.M.C. officer has the opportunity to decide whether he will remain in the corps or accept the gratuity of £1,000 after seven years' service and try his fortune in civil life. If he elects to remain he will between his eighth and twelfth year of service undergo a course of post graduate study at the Royal Army Medical College and the London hospitals of five months' duration followed by a course of study of a special subject selected by himself provided he has shown special aptitude in the post graduate course or during his previous service. During this period of study he remains on full pay and the fees of the courses are paid by the State. When qualified in his special subject the officer becomes entitled to specialist pay at 5s. a day when holding a specialist appointment. After this post graduate course the officer probably proceeds abroad again and promotion to major rapidly ensues and from that time onward the officer receives regular successive increases of pay and is eligible for additional and charge pay as well. The directorates of hygiene and pathology and the appointment of two serving officers as consultants in medicine and surgery have been instituted and have proved a marked success. All these appointments are of the rank of colonel or major general and were devised to permit specially selected officers to rise through all ranks to that of major general on the strength of their professional or purely scientific work. This side of the work of Royal Army Medical Corps officers is carefully watched by these directorates and consultants and not only ensures the maintenance of a high standard but enables the good professional work of individuals to be brought to notice.

Under these conditions the possibilities for good workers are very great in the Royal Army Medical Corps. There is scope for original research in tropical disease, in preventive medicine, and in bacteriology, as well as in the

large chemical field open to the specialist in medicine, surgery, or gynaecology, in venereal disease, and in ophthalmology. Child welfare is also undertaken systematically by officers of the Royal Army Medical Corps. At the same time, instruction in administration is continuous. The Royal Army Medical Corps is essentially organized for war, and one of the lessons of the great war was that trained administrators must exist to enable the fullest benefit to be obtained from professional talent. Many appointments carrying administrative responsibility are open to those officers who display capacity for this duty. All officers must be prepared to undertake command and to have a knowledge of army administration, especially in war. Equally important is the technical training of the non-commissioned officers and men of the corps in such "trades" as trained nurse, nursing orderly, masseur, radiographer, operating room assistant, laboratory assistant, hospital cook, dispenser, etc. This training is carried out by the officers and nursing sisters, and opens a large field for those who have ability in lecturing and teaching as well as the power of influencing men.

## Promotion

Promotion takes place automatically to captain after three and a half years' and to major after twelve years' service, provided the officer is qualified and recommended for promotion. Promotion to the higher ranks is by selection from those senior in the rank below but special promotion by brevet or otherwise is open to officers of the Royal Army Medical Corps.

## Pay and Allowances

The rates of pay and allowances are given in the accompanying Table A (see p. 428), they compare favourably with those that obtained before the late war.

## Additional Pay and Charge Pay for Officers of the P.A.M.C.

An officer not above the rank of lieutenant-colonel who is acting as a specialist receives up to 5s. a day according to subject or group of subject. An officer in charge of a hospital receives charge pay the daily amounts being: in excess of 50 beds 2s. 6d. in excess of 150 beds 5s. in excess of 300 beds 7s. 6d. in excess of 500 beds 10s. An officer in charge of a medical or surgical division of a general hospital with more than 300 beds receives half these rates. Senior medical officer Royal Arsenal not exceeding 10s. daily. Officer in command of the depot P.A.M.C. 5s. daily. The senior officer of the Army Medical Services with an army in the field a rate to be fixed by the Army Council according to the magnitude of the charge. The officer if under the substantive rank of colonel holding the appointment of senior medical officer in a command abroad or of a consultant director of medical services if the number of soldiers is 1,500 or upwards 5s. daily. Adjutant P.A.M.C. depot 5s. daily. Adjutant R.A.M.C. (T.A.) 2s. 6d. Further an officer graded as a specialist and appointed to the charge of a medical or surgical division of a general hospital may be allowed to retain his additional pay and to draw the rate of charge pay laid down for the officer in charge of a medical or surgical division of a general hospital provided that the total of additional and charge pay so drawn does not exceed the rate of charge pay drawn by the officer in charge of the hospital. With this exception charge pay and additional pay as specialist will not be payable concurrently.

## Retirement and Retired Pay

Retired pay will consist of two parts: (a) a service element based on the officer's total service; (b) a rank element for the rank from which the officer retires. An officer with less than twenty complete years' service will not be eligible for retired pay. The scale subject to the reduction of 6 per cent referred to below is for the service element £15 a year for each completed year of service as a medical officer. For the rank element the scale is as follows:

Rank from which Retired	After Completing 1 Year's Service in the Rank	After Completing each Additional Year's Service	Maximum Rank.
Major	£ 12	£ 12	£ 120
Lieutenant-Colonel	150	30	250
Colonel	200	50	350
Major-General	440	50	550
Lieutenant-General	600	50	650

The retired pay of an officer retiring with less than one complete year's service in the rank from which he retires will be assessed as though he had retired from the rank below.

TABLE A—Pay and Allowance

Rank	Pay per Diem*	Rations†	Servant	Married			Unmarried			Approximate Units Total		Approximate Yearly Total	
				Lodging	Fuel and Light (Average)	Furniture Allowance	Lodging	Fuel and Light (Average)		Married	Unmarried	Married	Unmarried
Lieutenant	£ s d 1 0 8	1 6	2 0	3 6	1 5	2 0	2 3	1 2		£ s d 1 11 1	£ s d 1 7 7	£ 567	£ 503
Captain	1 5 4	1 6	2 0	4 6	3 0	2 0	3 0	1 8		1 18 4	1 13 6	700	611
Captain after 8 years commissioned service	1 8 2	1 6	2 0	4 6	3 0	2 0	3 0	1 8		2 1 2	1 16 4	751	663
Captain after 10 years commissioned service	1 10 6	1 6	2 0	4 6	3 0	2 0	3 0	1 8		2 3 6	1 18 8	791	706
Major	1 15 4	1 6	2 0	4 6	3 0	2 0	4 0	2 3		2 8 4	2 5 1	882	823
Major after 15 years commissioned service	2 0 0	1 6	2 0	4 6	3 0	2 0	4 0	2 3		2 13 0	2 9 9	957	903
Major after 18 years commissioned service	2 2 4	1 6	2 0	4 6	3 0	2 0	4 0	2 3		2 15 4	2 12 1	1010	951
Major after 20 years commissioned service	2 7 0	1 6	2 0	4 6	3 0	2 0	4 0	2 3		3 0 0	2 16 9	1093	1036
Lieutenant Colonel	2 14 0	1 6	2 0	4 6	3 0	2 0	4 6	2 3		3 7 0	3 4 3	1273	1173
Lieutenant Colonel after 3 years commissioned service as such	2 18 10	1 6	2 0	4 6	3 0	2 0	4 6	2 3		3 11 10	3 9 1	1311	1251
Colonel	3 5 10	1 6	2 0	5 6	4 1	2 0	5 6	2 9		4 0 11	3 17 7	1477	1416
Major General	4 9 4	1 6	4 0	11 0	5 2	2 0	11 0	3 8		5 13 0	5 9 6	2052	1973

\* Pay Warrant rates as amended by Army Order 195/26 less 6 per cent from July 1st 1927 (vide Army Order 1 of 1927). The Pay Warrant rates are subject to revision to an extent not exceeding 20 per cent according to variation in the cost of living. The next revision may take place with effect from July 1st 1930.

† Rates of Allowances vary from time to time and issues are subject to conditions laid down in the Allowance Regulations.

The maximum rates of retired pay are as follows:

Captain and Subaltern	£300
Major	£450
Lieutenant Colonel	£600
Colonel	£800
Major General	£1,050
Lieutenant General	£1,200

The above rates are those laid down in the Pay Warrant. They have been reduced by 6 per cent as from July 1st, 1927. Further revision may take place triennially to an extent not exceeding 20 per cent, according to variation in the cost of living.

Officers with seven and less than twenty years service as medical officers may be permitted to retire with a gratuity in accordance with the following scale:

After 7 years service as a medical officer	£1,000
After 3 years service as a medical officer in the rank of major	£2,800
After 6 years service as a medical officer in the rank of major	£3,500

#### Seconded Service

An officer may be permitted to accept employment in the Foreign or Colonial Offices when so seconded he is not eligible for pay or allowances from army funds but his service continues to reckon towards promotion and under certain conditions, towards increase of pay, pension, or gratuity.

#### Service on the West Coast of Africa

Officers for service in West Africa are usually taken from a list of volunteers for such service. An officer at present receives, while actually serving in West Africa (which service may include ordinary leave not exceeding sixty-one days in a year and any time spent at Madeira or the Canary Islands on sick leave), additional pay at the following daily rates: lieutenant-colonel 12s, major 9s, captain 7s 6d, lieutenant 6s. Service on the West Coast of Africa also counts double towards voluntary retirement and the service element of retired pay under certain conditions, and also entitles to leave at home of one day for every two days' service after twelve months continuous service on the coast up to a maximum of 365 days leave. Continuous service includes the ordinary sixty-one days leave and any time spent in Madeira or the Canary Islands on sick leave for this purpose.

#### THE ARMY DENTAL CORPS

The corps is administered by the Director-General, Army Medical Services. It is a joint service for the Army and Royal Air Force, and the personnel is required to serve under either force and be interchangeable. Officers and other ranks posted for duty with the Royal Air Force will perform their duties under the regulations of the Royal Air Force for the employment of dental personnel, but the conditions in the following tables apply equally in either force. Promotion is carried out on one general list. The regulations for admission to the Army Dental Corps should be obtained from the Under Secretary of State, War Office, and carefully studied.

#### Officers' Appointment and Promotion

1 Commissions as lieutenants in the Army Dental Corps may be given to persons duly qualified under regulations approved by the Army Council.

2 An officer shall be eligible for promotion to the rank of captain on completion of three and a half years' service and to the rank of major on completion of twelve years' service in the corps provided he has previously qualified in such manner as may be prescribed by the Army Council.

3 Promotion to the rank of lieutenant colonel and colonel in fill the establishments laid down from time to time for those ranks shall be made by selection of the Army Council provided the officer has previously qualified for promotion to those ranks in such manner as may be prescribed by the Army Council.

4 Appointments are in the rank of lieutenant, except in cases where service of three and a half years or more has been given as a temporary dental officer, when the rank of captain will be given, provided the officer has qualified for promotion to that rank. Service as a temporary dental officer will count towards the three and a half years for promotion to captain, and the twelve years for promotion to major.

#### Pay

The following are the rates for officers of the Army Dental Corps:

	Per diem £ s d
Lieutenant	0 18 10
Captain	1 3 6
Captain after 8 years' total service	1 6 4
Captain after 10 "	1 8 2
Major	1 12 10
Major, after 15 years' total service	1 17 8
Major, after 18 "	2 0 0
Major after 20 "	2 4 8
Lieutenant Colonel	2 11 8
Lieutenant Colonel after 3 years' service as such	2 16 4
Colonel	3 3 6

These rates are 6 per cent below those shown in the Pay Warrant 1926, as amended by Army Order 195/26. The rates are subject to revision to an extent not exceeding 20 per cent according to variation in the cost of living. The next revision may take place with effect from July 1st, 1930.

#### Charge Pay and Allowances

The officer in charge of the Dental Laboratories Aldershot receives charge pay at the rate of 5s a day if holding the rank of captain or 2s 6d a day if holding the rank of major. The allowances for officers of the Army Dental Corps are at the same rates as for officers of the Royal Army Medical Corps.

#### Petirement and Retired Pay or Gratuity

The rates of retired pay will be the same as for officer of the Royal Army Medical Corps. Voluntary retirement on retired pay will not be allowed until after twenty years' service. Early retirement on gratuity may be allowed as follows: After eight and a half years' service as a dental officer gratuity of £1,000; after fifteen years' service £2,000; after eighteen years' service £3,000. Retirement will be compulsory at the age of 55 years. A dental officer who does not qualify for promotion within three and a half years' service in the corps will be retired, and a captain who fails to qualify for promotion to major within twelve years' service in the corps will be retired on any gratuity for which he may be eligible.

## ROYAL AIR FORCE MEDICAL BRANCH

The Air Council attaches great importance to attracting into the R.A.F.M.S. the best type of medical man. Success on the capacity of the medical service depends in a peculiar degree on the safety and efficiency of the Royal Air Force. The duties of these medical officers include not only the prevention and treatment of those ordinary diseases to which the personnel of any fighting service are liable, but the special study of the mental and physical stresses imposed on the airman in diverse circumstances and climates—a new branch of medicine which still provides considerable scope for research.

As promotion to the higher ranks of the service is by selection from officers who are eligible by reason of length of service, and as a certain proportion of the higher ranks will be reserved for purely scientific as opposed to administrative appointments, it will be seen that there are excellent prospects for the young medical officer who exhibits initiative and energy in scientific research as well as for those who develop a talent for administration. The work to be done therefore has a high professional interest which combined with good rates of pay and allowances offers a career for medical men which should prove both attractive and interesting. The life is one which is certain to appeal to the man of wide outlook who desires opportunities for travel, sport and games and can find interest and enjoyment in aviation. His duties will be a matter of course give him flying experience as a pilot, which is necessary for the proper study of the medical problems of aviation and for gaining first-hand knowledge of the conditions under which his comrades serve.

## COMMISSION

The establishment will consist partly of permanent and partly of short service officers.

An officer will on first entry be granted a short service commission for a period of three years on the active list (which may be extended to five years at the discretion of the Air Council) if the officer so wishes, on the recommendation of the Director of Medical Services) and of four years in the Reserve of Air Force Officers. Selections for permanent commissions will be made from officers holding short service commissions, and those who are not selected will be transferred to the Reserve at the expiration of their period of service on the active list.

For those entrants who desire it the prospect of obtaining a permanent commission is approximately an even one. Experience has so far shown that the officers selected have included the great majority of the desirous and suitable for retention in the service, owing to the fact that the short service commission with its gratuity after three or five years is in itself an attraction to many entrants who desire to enlarge their experience and outlook from the point of view of subequently entering private practice or who on entry have not made up their minds to the adoption of a permanent career in the service and subsequently find that they would prefer to return to civil life.

Medical officers may be allowed to count as service their time spent in resident appointments in civil hospitals under the following conditions:

(1) An officer granted a short service commission on or after July 1, 1923 who at the time of application for the commission holds or is about to hold a resident appointment in a recognized civil hospital may be seconded for the period not exceeding one year from the date when the commission is granted during which the appointment is held. If the applicant already holds the appointment when the commission is granted the commission may be antedated to the date on which the appointment was first held provided (a) that the appointment is held for not less than one year (b) that the period of secondment and the period of antedate shall not together exceed one year and (c) that the antedate shall not be made until the officer has joined for actual R.A.F. duty.

(2) An officer granted a short service commission on or after July 1, 1923 who has previously held a resident appointment in a recognized civil hospital for a period not less than one year may provided the commission is granted not more than six months after the termination of the hospital appointment be granted an antedate of the commission equal to the period of the appointment up to a maximum of one year.

(3) The term resident appointment as used at (1) and (2) may be held to include a period of not more than six months in a non-resident appointment immediately preceding or following a resident appointment.

(4) If necessary the ordinary maximum age for appointment to a commission may be increased by a period equal to any antedate granted under (1) and (2).

(5) An officer who has been seconded or whose commission has been antedated as above will be required to serve for a minimum period of three years on the active list from the date of joining for actual R.A.F. duty.

(6) Pay and allowances for period of secondment or antedate will not be allowable and such period will not be reckoned in the payment of gratuity payable to short service officers. Subject to (5) however such period will be reckoned as commission service in the Royal Air Force for purposes of seniority and promotion and in the case of permanent officer of retirement retired pay and retirement gratuity.

Officers who have been selected for permanent commissions may be permitted to attend for a period not exceeding nine months a postgraduate course in general medicine and surgery, tropical and preventive medicine and other special subjects. Such permission may be granted at any time when the exigencies of the service permit during the first sixteen years of service and when attending these courses officers will receive full pay and allowances.

All entrants in the R.A.F.M.S. will be commissioned as Flight Officers (Medical) and will be eligible for promotion to the rank of Flight Lieutenant (Medical) after two years' service. Officers selected for permanent commissions will normally be promoted to the rank of Squadron Leader after ten years' total service. Accelerated promotion may be granted in a limited number of cases to officers who show exceptional ability after the completion of eight years' service. Promotion within a flight lieutenant to the rank of Wing Commander will be by election at any period after sixteen years' total service and to that of Group Captain by election at any period after twenty-two years' service.

There will be no competitive examination on entry. Candidates must be under 23 years of age. British subjects, the sons of British subjects, and of our Empire descent and will be interviewed personally by the Director of Medical Services, Royal Air Force, before acceptance. Each candidate must produce:

1. Birth certificate
2. Medical registration certificate
3. A declaration containing the following information:
  - (a) Age and place of birth.
  - (b) That he is a British subject, the son of a British subject, and of pure European descent.
  - (c) That he is ready to engage for general service at home or abroad as required.
  - (d) The qualifications he is possessed of and what medical or other appointments he has held (if any).
  - (e) That he is willing to fly as a pilot or engineer when so called upon to do so.

Each candidate will be required before acceptance to pass a medical examination to ensure that he labours under no constitutional or mental disease or diseases or weakness, nor any imperfection or disability which may interfere with the efficient discharge of the duties of a medical officer in any climate, in peace or war.

On appointment entrants will undergo an initial course of eight weeks during which they will be given instruction in the special medical aspects of aviation, the organization and administration of the Royal Air Force, and the general and special duties to be performed by officers in the Medical Branch. In order to avoid the necessity for further examinations the position of entrants in order of seniority in the Air Force List will be determined at the end of the initial course by a system of marking and reports on the actual work done during their instruction.

## UNIFORM AND EQUIPMENT

Medical officers are required to provide themselves with the uniform service dress and mess dress of their rank and with the distinguishing badges of the Royal Air Force Medical Branch. The provision of full dress is entirely optional at present. An allowance of £2.0 towards the cost of uniform is made on joining to candidates who have not had previous commissioned service in H.M. Forces.

## PAY AND ALLOWANCES

The emoluments of medical officers of the Royal Air Force are given in outline below. The standard rates of pay and retired pay were drawn up on the basis of the high cost of living in 1919 and 20 per cent of each of the standard rate is detachable and subject to alteration either upwards or downwards as the cost of living rises or falls. Under this provision the current rates now in force represent a reduction of approximately 6 per cent on the standard rates. The next revision will take effect from July 1st 1930 and subsequent revisions will be made at intervals of three years.

## PETER D. PAY

The minimum period of service qualifying for retirement on retired pay is twenty years. Standard rates of retired pay are as follows:

**For Officers**—Air Vice Marshal, £780 to £1,010 per annum, Air Commodore, £650 to £950 per annum.

## Royal Air Force Medical Branch Rates of Pay and Allowances

Rank	Pay *			Cash Allowances at Home Rates in lieu of Quarters 1 a ions and Servant if not available in India (per annum) †		Pay plus Allowance (per annum)

Air Vice Marshal	5 0 0	4 14 0	1715 10 0	405 1 3	375 12 11	2191 11 3	2091 2 11

\* Except for periods of service under Indian administration. For such periods officers receive pay and allowances at rates and subject to conditions authorized from time to time by the Government of India.

† These allowances are issued only when accommodation, fuel and light ratings and personal attendance are not available in kind. Normally provision in this is available for junior officers. Married rates of allowances are payable only to married officers who have reached the age of 30 or the rank of squadron leader. A colonial allowance is granted in certain commands abroad.

The rates and general scheme of allowances are liable to revision as circumstances may require.

## Officers Below in Rank

Age on Retirement	Yearly Rate of Retired Pay	Years of Service	Addition for each extra Year of Service *	Deduction for each Deficient Year of Service *
40	£ 300	17	£ 15	£ 15
41	337	17	15	15
42	375	18	15	15
43	412	18	15	15
44	450	19	15	15
45	487	19	15	15
46	525	20	15	15
47	562	20	15	15
48	600	21	15	15
49	637	21	15	15
50	675	22	15	15
51	697	22	22	15
52	720	23	22	15
53	742	23	22	15
54	765	24	22	15
55	790	24	22	15

\* Limited to five years.

The maximum standard rates of retired pay and the compulsory retiring ages for the several ranks are

Rank	Yearly Rate of Retired Pay	Compulsory Retiring Age
Air Vice Marshal	£ 1010	69
Air Commodore	950	57
Group Captain	900	55
Wing Commander	600	51
Squadron Leader	500	48

## Gratuities

A permanent officer allowed to retire before having qualified for retired pay may be granted a gratuity provided he has not less than ten years' commissioned service—namely, £1,500 if he has ten but less than fifteen years' commissioned service, £2,500 after fifteen or more than fifteen years'.

Short service officers will be eligible on passing to the Reserve for gratuities on the following scale: £100 for each of the first two complete years of service, £150 for each of the third and fourth complete years, and £200 for the fifth complete year, that is, for three years' service on the active list £350, for five years £700.

These gratuities will not be payable to officers granted permanent commissions, but their service on a short service commission will count towards retired pay.

Further particulars may be obtained on application to the Secretary, Air Ministry (DMS), Adastral House, Kingsway W C 2.

## INDIAN MEDICAL SERVICE

THE Lee Commission, which visited India to inquire into the prospects and remuneration of the European Services, made certain recommendations with regard to the Indian Medical Service in its report issued in May, 1924. The recommendations received careful consideration by the Government of India and the Secretary of State, and the result the Secretary of State announced in the House of Lords that he had come to the conclusion that the recommendation of the Lee Commission that the military side of the Indian Medical Service should be absorbed in the R A M C would raise more difficulties than it would solve. He had therefore decided that the Indian Medical Service must be maintained as essential in a military service constituted on the same broad lines as at present.

In order to maintain the necessary war reserve for the Indian Medical Service, and also to provide European medical attendance for European officers of the army in civil services and their families, as recommended by the Lee Commission, a stated number of I M S officers will be lent to Provincial Governments for employment in posts, and the Provincial Governments will be required to employ them in addition to the officers of the Provincial Civil Medical Services, which are now to be constituted. The control of and recruitment for these Provincial Medical Services will be in the hands of the Provincial Governments.

ments but this will not of course affect a certain line of service of the I.M.S. officers but to them.

These are the broad outlines of the future organization of the medical services in India which have been announced but certain details of the scheme are understood to be still under consideration by the Secretary of State. It is expected that the final decision will be taken before very long.

In the meantime the Secretary of State is continuing to recruit for the Indian Medical Service on the system which has been in force since the last open competitive examination in July, 1915. Appointments are made by nomination and to assist him in making them the Secretary of State has constituted a Selection Committee, which summons and interviews such applicants as appear to be *prima facie* suitable, and makes recommendations for appointment. A similar committee has been appointed in India to investigate applications from candidates in India and to forward recommendations to the Secretary of State. All appointments are made under the special terms which are set out below.

#### Special Recruitment

The Secretary of State has announced his intention of appointing a certain number of medical men of British descent in the near future to permanent commission in the Indian Medical Service on the special terms set out below. Candidates must be well qualified medical practitioners over 24 and under 32 years of age. Appointment will be his nomination on the recommendation of a Selection Committee before whom candidates will have to appear in person. The special terms are as follows:

(a) On completing either six or twelve years' active service in India an officer so appointed may claim to retire on a gratuity of £1,000 or £250 respectively provided that he has given notice of his intention twelve months in advance. If he does not do so he will continue in the service on the ordinary pensionable footing. If an officer applies and is permitted to retire at any time between the completion of his sixth and twelfth years of service, or between the completion of his twelfth and seventeenth years of service, he will be eligible for a gratuity of £1,000 only or £250 only respectively. In addition to actual service only privilege leave (that is leave on full pay for six days in each year) will be allowed to count towards the period of six or twelve years required for the gratuity and no ordinary furlough or sick leave.

(b) Officers so appointed will be eligible for the concessions set forth in the Provisional Regulations except that no concession of passage will be granted before the completion of five years' service and then only if the officer has not given notice to retire in accordance with the preceding sub-paragraph. Otherwise he will be provided with a free passage for himself and his family to the United Kingdom or to any port in the British Empire to which he may wish to proceed on the completion of 12 years' service. Similarly on the completion of eleven years' service an officer will become eligible for a second concession of passage if he has not given notice as above or he will receive free passages to the United Kingdom or any port in the British Empire if he retires on completion of twelve years' service. Passages granted on retirement must be claimed within three months of the date of retirement. An officer invalided home on sick leave during his first twelve years of service will be granted a free passage but any such passages granted to him will count against any concession of passage or passages to which he may be entitled. But if he retires otherwise than on account of ill health before becoming entitled to benefits under the passage rules he will be required to refund the cost of the passages granted for sick leave.

In view of the reorganization of the Indian Medical Service which is now under consideration only military employment can be guaranteed to officers entering the I.M.S. at the present time. They will however be eligible for the benefits of any conditions regarding civil employment which may be made applicable to officers in future appointed to the I.M.S. as the result of decisions taken on the Lee Commission Report.

In all other respects the ordinary rules and conditions set forth in Regulations for the Appointment of Candidates to Commissions in the I.M.S. will apply. Officers retiring on a gratuity after twelve years' service will be liable equally with those retiring on pension to recall to military duty in case of emergency up to 55 years of age. They would only be recalled to duty in the event of an emergency which exhausts the capacity of the reserves permanently maintained in civil employ in India.

The officers appointed will sail for India early next year. It is hoped to arrange for them to attend a course of instruction before doing so.

Application forms and any further particulars desired may be obtained from the Secretary Military Department India Office, Whitehall, S.W.1. Envelopes should be marked Medical Recruitment.

#### PRISON MEDICAL SERVICE

Candidates for the medical staff are approved by the Secretary of State for the Home Office on the recommendation of the Prison Commissioners. The Chairman of the Board is Mr. M. J. W. C. B. Application for employment may be made to the Board on a special form, which can be obtained from the Secretary, Prison Commission Home Office London S.W.1.

In the smaller prisons the medical officer is usually a local practitioner but in the larger the members of the medical staff are required to devote their whole time to the service. In the case of those required to give their whole time to the service the appointment in the first instance is to the post of medical officer Class II, and from the seniors of this rank the medical officers Class I are selected as vacancies occur.

In February, 1923, the then Home Secretary appointed a committee to report on what changes if any, should be made in the remuneration or other conditions of service of officers at the prisons and Borstal institutions in England and Scotland and at Broadmoor Criminal Institute Asylum. Evidence was given on behalf of the British Medical Association by the Medical Secretary who pointed out that the salary offered to Class II medical officers—namely, a basic salary of £300 rising by annual increments—was even when the allowance and bonus was added, less than the £500 a year the Association held upon as the minimum commencing salary which should be given to a whole time medical man holding such a responsible office. The committee issued its report in November 1923. It recommended that officers of both classes should receive an additional £50 a year, and from a communication received from the Prison Commission we understand that the pay of the whole-time prison medical staff is: Medical officer Class II £350, rising by annual increments of £20 to £600; medical officer Class I £650 rising by annual increments of £25 to £800. Unfurnished quarters are provided or an allowance in lieu is made. The civil service bonus is paid on the salary. There are 15 medical officers Class II and 12 medical officers Class I and 23 part-time medical officers.

The number of vacancies is never large, and promotion is slow.

#### MEDICAL PRACTICE IN BRITISH DOMINIONS AND FOREIGN COUNTRIES

Medical Acts have now been passed in almost all places forming part of the British Empire beyond the seas and registers of duly qualified practitioners are consequently maintained. To these registers medical men educated in the United Kingdom are always admissible merely on payment of a registration fee providing they produce evidence that they are of good repute and are either registered or eligible for registration in the United Kingdom as the local requirement may be. The only exception in this statement that need be made relates to the Dominion of Canada. Each of its provinces acts as a medical or an independent State. The result has been that reciprocity of practice has in the past been established between this country and all the provinces of Canada except British Columbia where certain obstacles still remain to be overcome. It has however to be recorded that reciprocity with Saskatchewan and New Brunswick has recently been brought to an end by those provinces and the arrangement with Quebec is also likely to be ended shortly owing to their action. We would advise any medical man proposing to practise in Canada first to communicate with the Provincial Registrar stating what degrees or diplomas he holds and asking for information as to the precise steps he must take in order to obtain admission to the Provincial Register. The Licence of the Dominion Council which can only be obtained after examination entitles its holder to practise in any of the provinces of Canada though in regard to Quebec there is a proviso that he must have been registered in the province five years prior to the application for the recognition of the Dominion Licence. In order to sit for the examination for the Dominion Licence it is necessary to obtain a licence from one of the provinces but this can be obtained from one of those with whom reciprocity has been established.

Italy and Japan are the only two foreign States with which complete medical reciprocity has been established though there are other countries which grant a limited recognition to British qualifications. Generally speaking, in Continental countries (with the exception of the kingdom of Italy) a British medical man desiring to exercise his profession therein must pass practically the same examinations as those imposed on natives of the country. The same obligation applies to all foreign States in the South American continent. Each of the United States of North America has its own laws and regulations governing medical practice, and all of them require the holder of a British qualification to submit to an examination. The States of New York and Indiana require an applicant to be naturalized.

A pamphlet showing the conditions under which medical and dental practitioners legally qualified in their own country may practice abroad can be obtained from the office of the General Medical Council, 44, Hallam Street, Portland Place, London W.1 price 2s. 6d. or 2s. 9d. post free in the United Kingdom. Practitioners who think of going abroad to practice will find therein much useful information, including the name of the official in each country to whom requests for further particulars should be addressed. A new edition in which all the information has been brought up to date has just been published (1927).

### MEDICAL APPOINTMENTS IN THE COLONIES AND MANDATED TERRITORIES

Medical appointments in the self-governing Dominions and the territories under their control, and in Southern Rhodesia, are made by the Governments concerned, and are not in general open to candidates in the United Kingdom. Appointments to the medical services of the colonies and other territories under the administrative direction of the Colonial Office are, apart from those in Ceylon, Mauritius, Jamaica, Barbados, the Bahamas, Bermuda, and Malta, which are filled locally, made by the Secretary of State for the Colonies in this country. Such appointments are to a given colony or colonies for there is no unified service directly administered from the Colonial Office. It follows that conditions of service and superannuation are in the main determined by the economic resources and general public health policy of the individual colony and its local Government and vary almost as widely as do conditions of climate. Moreover, the extent of the control exercised by the Colonial Office varies according to the constitutional forms of the particular colony, and the detailed information available centrally is not always either up to date or complete. The intending candidate, therefore, should make exhaustive inquiries as to local conditions, and particularly as to facilities for private practice where this is included in the terms of appointment. He will also do well to supplement official information by reference to the central office of the British Medical Association where reports obtained from time to time from the local Branches are available. This is the more necessary because facilities for transfer from the Medical Service of one colony to that of another are as yet practically non-existent except in connexion with a few specialist and senior appointments; thus sets strict limits upon the opportunities for promotion.

To the physically and mentally suited for the climatic and social conditions peculiar to the various colonies the Colonial Medical Services should, and in some cases do, offer a field of professional activity rich in interest and in opportunity for pioneer work. The scope for research is wide and facilities for its prosecution are beginning however tardily to be provided. An increasing number of specialist posts is becoming available in the larger services, and the general policy is to fill them by promotion of suitably qualified junior officers. The potentialities of sanitation are beginning to be appreciated by local administrations, however vaguely. But all these advantages have to be weighed against the fact that in the Colonial Medical Services the opportunities for promotion are limited. In some instances indeed they are almost entirely absent. Hence the necessity for a full inquiry before accepting appointment. It is

true that the post-war economic stringency to which the delay of essential reform was usually attributed is giving place to more favourable conditions. There are also signs of increasing parliamentary and departmental interest in the development of a sound health policy. Amongst these the most significant is perhaps the recent appointment by the Secretary of State in consultation with the Medical Research Council, of a Committee "to advise the Secretary of State and the Medical Research Council upon the initiation and promotion of medical research in the interests of the Colonial Empire, upon the recruitment and conditions of service of the necessary personnel, and upon the management and allocation of any funds available for the purposes." The appointment of a chief medical adviser to the Secretary of State for the Colonies has also had its effect. We are confident that the work of this officer will contribute greatly to the establishment of conditions making for efficiency and well-being in the Colonial Medical Services. Meanwhile, those services are too often hampered by conditions which make efficiency unattainable. At the worst they are in some colonies starved of material resources in the name of economy, underpaid, and underpaid, with inadequate facilities for study leave and at the mercy of an administration in which the nominal head of the service has no effective voice. Hence the urgent necessity for making careful and sufficient inquiry as to the position in any given service before appointment is accepted.

The medical services recruited in this country by the Secretary of State for the Colonies include those of West Africa, East Africa, Malaya, Hong-Kong, the West Indies, Fiji and the Western Pacific Colonies, and Palestine, besides a number of small services offering individually one or two appointments at an inadequate remuneration and with no prospects of promotion. The recent revision of the conditions of the Fiji Medical Service shows a distinct improvement in this colony. The basic salary of the district medical officers is £500 by £25 to £725, and although this is below the £600 minimum recommended as adequate by the British Medical Association this fact is offset by the concession of allowances of from £175 to £275 in five of the districts, the value of private practice in the remaining seven being estimated at from £200 to £600 a year. The services in the West Indies and some of the smaller colonies have not yet conceded the £600 minimum commencing salary, and whilst facilities for remuneration in private practice, general conditions of service, and a relatively low cost of living must in some instances be taken into consideration, these compensations are by no means universal. The services in the Leeward and Windward Islands are in a condition which requires special notice in a way of warning.

In general, candidates for these services must be between the ages of 23 and 35, although these limits are not at the moment absolute. A candidate over 35 years of age if accepted for appointment, may be required to serve on a temporary and non-pensionable footing, regular appointments are, subject to a varying period of probation, for the most part classed as permanent and pensionable. There is no entrance examination, but prior to selection for appointment must obtain a certificate of physical fitness from one of the Medical Advisers of the Colonial Office. Post-graduate experience in the medical services is desirable, and in some cases special allowances are conceded to the holders of a D.P.H. or other additional qualifications. Since 1914 candidates for the West African Medical Staff, the East African Medical Service, and the Malayan Services are, in general required to undergo an approved course of instruction in tropical medicine. The cost of this subject to a minimum of £100 of service being performed, is met by the Colonial administrations.

The bulk of the appointments made by the Secretary of State in this country are to the West African Medical Staff, the East African Medical Service, and the Malayan Services in Malaya. There are the stated that the services numerically, and therefore offer room for advancement. The better prospects of promotion and of specialist appointments than in the smaller services.

## WEST AFRICAN MEDICAL STAFF

This is amongst the best organized and best paid of the Colonial Services, though at present it appears to be undervalued. The territories covered by the service include Nigeria, the Gold Coast, Sierra Leone and the Cameroons. Climatic conditions vary considerably over this area but they are in general admittedly trying. This fact is at present recognized by the provision of more frequent leave periods than are usual elsewhere. The growing opinion that conditions are less adverse than they have been in the past is marked by a proposal to extend the tours of service. This proposal has not however found favour with the authorities for the time being. The rate of pay for a medical officer is £660 on appointment rising by annual increments to £860. There are in addition certain seniority and duty allowances, and there are a number of specialist and administrative posts carrying relatively high salaries. The pension after 18 years' service is £570. Gratuities of £1,000 or £1,250 may be drawn on retirement after 9 or 12 years' service. Members of the West African Medical Staff are not permitted to take their wives or young children to the West Coast until they have acquired experience of the conditions of life and have obtained the sanction of the Governor. In the case of young children this is only exceptionally given.

## EAST AFRICAN MEDICAL SERVICE

This service includes Kenya, Uganda, Tanganyika Territory, Nyasaland, Zanzibar, and British Somaliland. In East Africa there is very wide scope for clinical work, both medical and surgical, as well as for research and for preventive medicine and sanitation. The service as a whole is fully alive to its responsibilities and opportunities, individual initiative is encouraged, and the career of a medical officer depends, not on seniority alone, but to a large extent on his own capability. As a rule it is preferable that medical officers on first appointment should not be married, although in all but a few stations conditions allow a medical officer's wife to accompany him. The service includes a medical and a sanitary division. The former is open to those holding ordinary medical and surgical qualifications, post-graduate experience in a hospital appointment being an advantage; posts in the sanitary division will as far as possible be filled by those holding a Diploma in Public Health. Climatic conditions vary considerably. In the greater part of Kenya they approximate more to the temperate than the tropical zone, but there are some areas in the East African Dependencies where conditions more closely resemble those in West Africa. The rate of pay for a medical officer is from £600 on appointment, rising by annual increment of £30 to £840, and thereafter subject to an efficiency bar at the point, by £40 to £920. Holders of the D.P.H. receive a special concession of two increments on appointment thus reaching the maximum of the grade two years earlier than they would otherwise do. Private practice may be permitted in certain circumstances, but there is no right to private practice even in those stations where opportunity for such practice may exist.

Whilst a candidate can only apply for appointment to the East African Medical Service in general and is liable to transfer between the several dependencies he may express his preference for any particular colony and his wishes will be informed by him as far as possible. As a rule transfer only takes place on promotion or at an officer's own request. The gratuities payable on retirement after nine or twelve years' service are similar to those for the West African Medical Staff. An officer retiring after twenty years' service at the maximum of the grade of medical officer receives a pension of £923 a year.

## MEDICAL SERVICES IN MALAYA

These services cover the Straits Settlements, the Federated Malay States, and some of the unfederated States. Certain reforms have recently been effected in the Malayan Services, and whilst that in the Federated Malay States still suffers from the inclusion of the Medical Department in the general decentralization of administration carried out since the war the commencing salary of 500 dollars a month, plus an allowance of 10 per cent for single and 20 per cent for married officers is generally

considered adequate. A non-pensionable allowance of 100 dollars a month is paid to officers holding the Diploma in Public Health. The service would now offer considerable scope to suitable candidates.

## SUDAN MEDICAL SERVICE

This service is a department of the Sudan Government, and includes a number of Sudanese medical officers and a number of assistant medical officers who are natives of the Sudan. The British medical inspectors are from the outset senior to all other medical officers. The Sudan is entering on a period of rapid development and expansion to which the medical services of the country must necessarily make an important contribution. The service offers ample opportunities for specialization and for research as well as for general medical and surgical work. The ordinary duties of a medical inspector may be summarized as follows:

- (1) To act as a consulting surgeon and obstetrician in all cases submitted to him by his medical staff. This necessitates considerable surgical experience.
- (2) To initiate, organize, and supervise all medical and sanitary work in his province. This includes extensive antimalarial work and often the supervision of large irrigated areas.
- (3) To carry out the medical supervision of schools and the examination of candidates for Government service and pension.
- (4) To train assistant medical officers and native sanitary overseers and to advise and direct medical officers in the carrying out of their duties.

(5) Probably, at a later date, to take part in teaching at the School of Medicine at Khartoum.

The climate varies, but is not in general unfavourable though hot. In the northern desert the nights are cool, even in the summer, in the central there is a rainy season of about four months, during which large areas become malarious. The southern area is more tropical in character, and mosquito-protected houses, nets and protective quinine are essential during the greater part of the year though the winter months are cool and pleasant. It is not considered desirable for medical inspectors to be accompanied by their wives until they have gained some knowledge of the language and the general conditions of life.

The commencing pay of a medical inspector is £1,720. On confirmation of appointment and success in the requisite examinations in Arabic the salary is increased by periodic increments to £1,200. There are four senior administrative posts carrying higher salaries. There is a compulsory contribution of 5 per cent of pay towards pension, which for a medical inspector, amounts after twenty years' service to £1,500 a year.

## PALESTINE

A few of the senior posts in the Health Department of the Government of Palestine are recruited in this country. The scales of pay vary between £1,550-25-750 for an assistant senior medical officer and £1,120 for the director.

## OFFICIAL SOURCES OF INFORMATION

All inquiries in connexion with medical appointments in the self-governing Dominions and their dependencies should be addressed to the High Commissioners or Agents General for the Dominions. Intending applicants are also recommended to consult the Colonial Office List which may be seen at the Colonial Office Library or at the central office of the British Medical Association of 220, 10, 11, 12, 13, 14, 15, 16, 17, 18, 19, 20, 21, 22, 23, 24, 25, 26, 27, 28, 29, 30, 31, 32, 33, 34, 35, 36, 37, 38, 39, 40, 41, 42, 43, 44, 45, 46, 47, 48, 49, 50, 51, 52, 53, 54, 55, 56, 57, 58, 59, 60, 61, 62, 63, 64, 65, 66, 67, 68, 69, 70, 71, 72, 73, 74, 75, 76, 77, 78, 79, 80, 81, 82, 83, 84, 85, 86, 87, 88, 89, 90, 91, 92, 93, 94, 95, 96, 97, 98, 99, 100. Available and the Professional Handbook (price 9d.) issued by the Overseas Settlements Office, Caxton House, Tenthill Street, London S.W.1.

Recent developments seem to suggest the possibility of a few appointments becoming available under the Egyptian Government. Questions about any such appointments should be addressed to the Director General, Public Health Department, Cairo.

Inquiries as to vacancies and conditions in the Sudan Medical Service should be addressed in the first instance to Dr. T. D. Acland, 19, Brimston Square, London, W.1.

All inquiries in connexion with Colonial medical appointments made by the Secretary of State for the Colonies, or

£E=£1 0s 6d sterling. This figure represents exchange value, no other currencies.

such vacancies as may occur in Iraq, Palestine, or Aden, should be addressed to the Private Secretary (Appointments) Colonial Office, 38, Old Queen Street, London, S.W. 1.

There is a number of medical appointments made by mining companies and other commercial undertakings in various parts of the tropics. Much caution should be exercised in accepting such posts, and the form of contract should be subjected to very careful scrutiny. Advice in this connexion should always be sought from the Medical Secretary's Department of the British Medical Association, British Medical Association House, Tavistock Square, London, W.C.1.

## MEDICAL RADIOLOGY AND ELECTROLOGY

### THE CAMBRIDGE DIPLOMA

A DIPLOMA in Medical Radiology and Electriology is granted by the University of Cambridge. The primary object is to provide adequate training in a branch of medical work which is becoming increasingly important and difficult, and which is outside the ordinary medical curriculum. The diploma is open only to those who hold a medical qualification, and includes a course of lectures and practical work in Physics (Part I) and in Radiology and Electriology (Part II). Attendance at the necessary courses of lectures in both subjects, and in addition six months' clinical experience in an adequately equipped hospital recognized by the Diploma Committee, is essential. The whole course of study takes six months, the lectures, practical work, and hospital attendance running concurrently.

The courses carried out by the University of Cambridge are at present arranged to begin early in January. Three months are spent at Cambridge doing the lectures and practical work in Part I, and attending the systematic lectures in Part II and the practice of Addenbrooke's Hospital, where there is a fully equipped and up-to-date x-ray and electriological department. The remaining three months can be completed at any hospital recognized by the Diploma Committee for this purpose, a list of which can be obtained, but special arrangements are made for students to continue their studies in London, where demonstrations in various hospitals are arranged, in order to give a wide experience.

In addition an independent six months' course is arranged by the British Institute of Radiology. This course is held entirely in London, but is recognized by the University as qualifying for the examination, it begins early in October.

Further particulars as to the Cambridge courses can be obtained from C. Stead, M.A., Cavendish Laboratory, Cambridge, and of the London courses from Stanley McKillop, M.D., at the Offices of the British Institute of Radiology, 32, Welbeck Street, London, W.1.

### THE FORTHWORTH DIPLOMA

Candidates for the Diploma must be graduates in medicine and surgery of the University of Edinburgh, or hold corresponding registrable degrees or qualification from some other licensing body. Candidates are not admitted to the examination for the Diploma until after the lapse of not less than one year from obtaining a registrable qualification, which qualification must be registered before admission to the examination.

The course of study begins in October and extends over a period of not less than three terms. The examination, which is written, oral and practical, is in two parts: (a) Physics and (b) Radiology. The examination is held twice yearly—namely July and October. Full particulars may be obtained from the Dean of the Faculty of Medicine.

## MEDICAL MISSIONARIES

MISSIONARY SOCIETIES are in constant need of qualified men and women to fill vacancies as they occur in their hospitals, and to enable them to take advantage of fresh opportunities. To the suitably endowed the mission field offers unique opportunities for interesting work and the development of native medical schools, as training hospitals in connexion with some of the larger mission

hospitals, affords excellent scope for valuable work to medical men and women who are qualified to teach. It is not usually expected that medical missionaries should take a position such as would otherwise be occupied by an ordained clergyman or minister, but it is essential that they should be prepared to exert their influence in any hospital to which they may be sent so that a Christian atmosphere may be maintained and the work of evangelization be carried on through the ministry of healing.

As for scientific and other qualifications for the work, medical missionaries, in addition to being physically capable of sustaining a life which makes a great demand upon their strength, should be thoroughly well trained physicians and surgeons. It is very desirable that they should have held a resident appointment at a general hospital, and have a good knowledge of practical surgery, gynaecology, tropical medicine, and the treatment of eye diseases. Useful information can be obtained from the secretaries of the various Missionary Societies, or from Thomas Cochrane, M.B., C.M. Honorary Secretary, British Advisory Board on Medical Missions, 1, Tudor Street, London, E.C.4.

## Dental Surgery.

UNTIL the passing of the Dentists Act, 1921, the profession of dentistry in this country was regulated by enactment very closely similar to those relating to the practice of medicine—that is to say, there was no direct prohibition of the act of practice; and the Dentists Act of 1878 gave the same degree of protection to legally qualified and registered dentists as was accorded to registered medical practitioners—namely, the reservation of the use of certain titles. This Act also provided (1) that no person should take or use the name or title of "dentist" (either alone or in combination with any other word or words) or of "dental practitioner," or any other name, title, or description expressed in words or by letters, implying that he was specially qualified to practise dentistry, unless he was registered, under a penalty of £20, and (2) that an unregistered person could not recover any fee or charge in respect of any dental operation attended or advised. But, in the case of the practice of medicine by unqualified and unregistered persons, certain deterrent factors came into play—such as the inability to give a death certificate—and these did not operate to the same extent in the case of dentistry, hence, unqualified practice was far more prevalent in dentistry than in medicine, and increased after a decision of the House of Lords placing a narrow interpretation upon the words "specially qualified to practise dentistry," by defining the word "qualified" as not referring to competence but to the possession of a recognized diploma.

### THE DENTISTS ACT, 1921

This unsatisfactory position has now been remedied by the passing into law of the Dentists Act, 1921. Its provisions are based largely on the recommendations of a departmental committee appointed in 1917 by the Privy Council "to investigate the extent and gravity of the evils connected with the practice of dentistry and dental surgery by persons not qualified under the Dentists Act." Since November 30th, 1922, no person has been permitted to practise or hold himself out, whether directly or by implication, as practising or as being prepared to practise dentistry unless he is on the *Dentists Register* provided for by the Dentists Act, 1878. The practice of dentistry defined as including, "the performance of an such operation and the giving of an such treatment attended or advised, as is usually performed or given by dentists, and the performing of any operation or the giving of treatment, advice, or attendance on or to any person, which is preparatory to or for the purpose of or in connection with the fitting insertion, or fixing of artificial teeth." The maximum penalty incurred by an offence is £100 for each offence. There are, however, important exceptions to the requirement of registration. A registered medical practitioner may practise dentistry without being on the *Dentists Register*, and a person

pharmaceutical chemist or chemist and druggist may extract a tooth where the case is urgent and where no doctor or dentist is available, but the operation must be performed without any kind of anæsthetic further any person may carry out minor dental work in a public dental service under the personal supervision of a registered dentist provided it is in accordance with conditions approved by the Minister of Health after consultation with the Dental Board.

Certain persons other than those qualified by examination were entitled to be registered under the new Act. They had to be of good personal character and 25 years of age before July 28th 1921 (the commencement of the Act) and to have been engaged for five of the seven years preceding that date as their principal means of livelihood in the practice of dentistry in the British Isles or have been admitted to membership of the Incorporated Dental Society not less than one year before the commencement of the Act. The passing of the prescribed examination in dentistry within two years of the commencement of the Act was considered as equivalent to practising for five years and a registered pharmaceutical chemist or a chemist and druggist who immediately before the commencement of the Act had a substantial practice as a dentist including all dental operations was treated as though he had practised for five years. A dental mechanic who for the five years had been carrying on his work as such and has secured the entry of his name on the list of candidates for examination can be registered provided within ten years of the commencement of the Act he passes the prescribed examination. The Board however has no power now to consider any further applications under this Act.

Dentistry may be carried on by a corporate body provided the majority of the directors and all the operating staff are registered dentists and that no business other than dentistry or only some business ancillary to dentistry is carried on by the company. Companies carrying on the business of dentistry at the present time are permitted to continue to do so with certain restrictions provided that the name of the company as well as the names of the directors have been entered in a list kept by the Registrar for that purpose. Every director or manager of a company convicted of an offence under the Act will be held to be guilty of the offence unless he proves that the offence was committed without his knowledge and the court may in addition to a fine order that the name of any director convicted shall be removed from the list of directors aforesaid.

A subsequent Act passed in 1923 made provision for the registration of persons who were 21 in November 1921 who had served during the late war in His Majesty's Forces and were on that date engaged as their principal means of livelihood in the practice of dentistry in the British Isles. The Board however has no power now to consider any further applications under this Act.

#### THE DENTAL BOARD

The Dental Board of the United Kingdom was established for the purpose of administering the new Act. The first members of the Board, who held office for three years, were all appointed but their term has now come to an end. The Board consists of the chairman appointed by the Privy Council, three members appointed by the General Medical Council who must be members of the Branch Councils for England, Ireland, and Scotland respectively, three persons who are neither medical practitioners nor dentists, appointed to represent England, Scotland and Ireland, and six elected members, one of whom represents the qualified dentists in England and Wales, one those in Scotland, and one those in Northern Ireland and two all the dentists registered under the Acts of 1921 and 1923.

On the establishment of the Dental Board in 1921 certain powers and duties of the General Medical Council were transferred to it, including the duty of erasing from the *Dentists Register* any entry which has been incorrectly or fraudulently made. An inquiry into the case of a person alleged to be liable to have his name erased from the *Register* is made by the Board which reports its findings to the General Medical Council the order directing the erasure being made by the Council. A name erased from the *Register* can only be restored by the Council upon a report made by the Board. An appeal to the High Court may be made by any person aggrieved either by refusal of the Board to register his name or by the removal of his name from the *Register*. The administrative expenses of the Board are defrayed from the registration fees and annual retention fees, but any surplus may be allocated to purposes connected with dental education and research or to any public purpose connected with dentistry. The office of the Dental Board is at 44, Hallam Street, London, W. 1.

The *Dentists Register* for 1927 contains the names of 14,355 persons, of whom less than a half are registered with

qualifications, 7,626 names having been registered under the provisions of the Dentists Acts 1878, 1921 and 1923, and 6,469 with medical surgical or dental qualifications.

#### DENTAL EDUCATION AND EXAMINATION

The preliminary examination in arts is the same for medical and dental students and the early stages of their education embrace much the same subjects and, as the dental student is required to obtain a knowledge of the broad principles of medicine and surgery, it is necessary for him to pursue some portion of his studies at a medical school as well as at a special dental school, the latter not undertaking the teaching of these subjects. Registration as a dental student is not in all cases compulsory though it is to be advised as convenient as affording proof of the commencement of professional education and it is required by most of the licensing bodies all of whom insist upon a curriculum covering four academic years.

Degrees in dentistry are granted by the Universities of Bristol, Durham, Leeds, Liverpool, Sheffield, Queen's University Belfast and the National University of Ireland as will be found cited in the articles on these universities. Licences in dentistry entitling the holder to be registered on the *Dentists Register* are granted by the Universities of Birmingham, Bristol, Durham, Leeds and Belfast, and by the Royal Colleges of Surgeons of England and Edinburgh and of Ireland and by the Royal Faculty of Physicians and Surgeons of Glasgow.

Recognized dental schools are numerous. In London there are those connected with the Royal Dental Hospital, Leicester Square, the National Dental Hospital, now the University College Hospital (Dental School), Great Portland Street, Guy's Hospital, King's College Hospital and the London Hospital. In the provinces there are the Birmingham Dental Hospital, the Royal Infirmary and the General Hospital, Bristol, the Dental Hospital and the Public Dispensary, Leeds, the Dental Hospital, Liverpool, the Dental Hospital, Manchester, the Dental Hospital and School, Newcastle-on-Tyne, the Royal Hospital, Sheffield. In Scotland there are the Dental Hospital, Dundee, the Incorporated Dental Hospital and School, Edinburgh and the Incorporated Dental Hospital, Glasgow, and in Ireland the Incorporated Dental Hospital of Ireland and the Royal College of Surgeons in Ireland. A list of dental schools and their officials will be found in the article on the General Medical Council at page 358.

There are considerable variations in the order in which the different licensing bodies require the various subjects of the curriculum to be taken up and every prospective dental student should study not only the regulations of the General Medical Council but also those of the body whose licence he hopes to obtain. This is the more important as in the case of some licensing bodies changes in the curriculum have been made or are contemplated.

All who think of becoming dentists may be advised to study a Memorandum lately drawn up for their guidance by the Registrar of the Dental Board setting out in convenient form and in untechnical language information for which request is frequently made to the Board.<sup>1</sup> It will be seen from this pamphlet that in order to assist suitable students the Dental Board has instituted a system of bursaries to pay the fees of those who have not the financial means to qualify and in some cases maintenance is given as well. Detailed information regarding these exceptional facilities may be had from the Registrar of the Board at the address given above. The passing of the Dentists Act, 1921, together with the disciplinary and other action taken by the Dental Board have already much enhanced the status of dentistry which is now taking its proper place among the learned professions. In these circumstances a large increase in the number of dental students is desirable. The prospects are bright for those who take up their studies in the near future. The importance of dentistry to health is being more realized every day and in consequence an increasing demand for the services of dentists may be confidently anticipated.

#### Recommendations of the General Medical Council

The Dentists Act still leaves to the General Medical Council the duty of controlling the course of study and examinations required for dental qualifications.

The following recommendations as to the course of study

<sup>1</sup> See the Registrar's Memorandum on Students' Preparation printed in the article on the General Medical Council at page 287.

<sup>2</sup> Memorandum by the Registrar on the Procedure to be Adopted by Those who Desire to Enter the Profession of Dentistry with Notes on Costs and Prospects, 1927. Dental Board of the United Kingdom, 4, Hallam Street, W. 1. Price 1s. post free.

and examinations to be required of candidates for degrees or licences in dentistry or dental surgery were adopted by the Council on May 27th, 1922

#### *Preliminary Examination and Registration*

1 That every dental student shall, at the commencement of his studentship be registered in the manner and under the conditions prescribed for medical students

2 That before registration in the *Dental Students Register* every applicant shall be required to have passed, in addition to the examination in general education, which shall be the same as that required for medical students, an examination in Elementary Physics and Elementary Chemistry, conducted or recognized by one of the licensing bodies which shall also be the same as that required for medical students

3 That before registration as a dental student every applicant shall produce evidence that he has attained the age of 17 years

#### *Professional Study*

4 That every candidate for a degree or licence in dentistry or dental surgery shall be required before admission to the final or qualifying examination to produce certificates showing

(i) That he is at least 21 years of age

(ii) That he has been registered as a dental student

(iii) That he has, subsequently to the date of registration as a dental student, been engaged in professional study for at least four years, of which three years at least shall be spent at a school or schools recognized for professional study by one of the licensing bodies

(iv) That, subsequently to the date of registration as a dental student, he has attended at a recognized medical school courses of instruction, which shall be the same as those required for medical students, in the following subjects: (a) Chemistry and (b) Physics, in their application to medicine, (c) Elementary Biology. That he has attended at a recognized medical school courses of instruction in the following subjects: (d) Human Anatomy (with dissections and demonstrations) for three academic terms, (e) Physiology (with laboratory instruction, including Practical Histology) for two academic terms, (f) General Pathology (including Bacteriology) for two academic terms, (g) Medicine for two academic terms, (h) Surgery for two academic terms. (i) the practice of a recognized general hospital or hospital of not less than eighty beds, with certified instruction in Clinical Medicine and Clinical Surgery, for four academic terms

(v) That he has attended at a recognized dental school courses of instruction in the following special subjects: (a) Dental Anatomy and Physiology, human and comparative. The course should comprise a minimum of twenty meetings of the class. (b) Practical Dental Histology and Morbid Histology. The course should comprise a minimum of sixteen meetings of the class. (c) Dental Pathology and Surgery. The course should comprise a minimum of twenty meetings of the class. (d) Dental Materia Medica and Therapeutics. The course should comprise a minimum of sixteen meetings of the class. (e) Dental Metallurgy (with practical work and demonstrations). The course should comprise a minimum of twenty meetings of the class. (f) Dental Mechanics (with practical work and demonstrations). The course should comprise a minimum of twenty meetings and twenty demonstrations. (g) A course of instruction in the use of Anaesthetics, general and local employed in dental practice. (h) A course of instruction in Radiology as applied to dentistry

(vi) That he has for at least twenty four calendar months attended, during the ordinary academic terms the practice of a recognized dental hospital or of the recognized dental department of a general hospital

(vii) That he has received for not less than twenty four calendar months, or for 2,000 hours, practical instruction in dental mechanics

#### *Professional Examinations*

5 That the examination for a degree or licence in dentistry or dental surgery shall be partly written, partly oral, and partly practical and shall include the following subjects: (a) Chemistry, Physics, and Biology, in their bearing on Medicine and Dentistry, (b) Human Anatomy and Physiology, (c) General Pathology, including Bacteriology, (d) Medicine and Surgery, (e) Dental Anatomy and Physiology, Dental Pathology, Dental Surgery (including Orthodontics), Dental Materia Medica and Therapeutics, and Dental Mechanics and Dental Metallurgy, (f) Practical Examination in Dental Surgery, (g) Practical Examination in Dental Mechanics and Metallurgy, (h) Anaesthetics, general and local employed in dental practice

6 That the prescribed subjects of examination may be combined or distributed at the discretion of the licensing bodies, and may be taken at two or more successive stages during the course of professional study provided that no candidate shall be admitted to any final examination in dental surgery and dental mechanics until he shall have completed the required four years' course of study

### ACKNOWLEDGEMENT

In detailed information published in this Educational Number of the *BRITISH MEDICAL JOURNAL* for the benefit of intending students of medicine and newly qualified practitioners has been revised throughout with the co-operation of the deans and secretaries of the medical schools and kindred institutions and of officials in the several public services, to all of whom we wish to acknowledge our indebtedness

### DEATH REGISTRATION

THE Births and Deaths Registration Act, 1926, which came into force on July 1st last, makes alterations in the manner of certification of deaths and the disposal of bodies. The new provisions were fully explained in an article published in this *JOURNAL* of June 18th (p. 1118). We shall here refer only to the medical practitioner's duty in respect of the delivery of the death certificate.

Under the Births and Deaths Registration Act of 1874 a registered medical practitioner was required, in the case of the death of any person who had been attended by him during the person's last illness, to give a certificate stating to the best of his knowledge and belief the cause of death. Hitherto the custom has been for the certifying medical practitioner to hand the certificate to a person liable to act as informant of the death for registration purposes, usually a relative or friend of the deceased. The difference in this respect made by the new Act is that henceforth it will be the duty of the medical practitioner to give such person only a written notice that he has signed the death certificate. The words of the Act are, that every such certificate

"shall be delivered forthwith by the registered medical practitioner by whom the certificate is signed to the registrar, and the registered medical practitioner, on signing a certificate as aforesaid, shall give in the prescribed form to some person required by the Births and Deaths Registration Acts, 1836 to 1901, to give information concerning the death, notice in writing of the signing of the certificate, and that person shall, except where an inquest is held on the body of the deceased person, deliver the said notice to the registrar."

The practitioner appears to have two alternative modes of fulfilling the obligation to deliver the certificate to the local registrar: direct, he may himself hand it to the registrar or he may post it in an official franked envelope supplied to him by the registrar. Posting is recognized in other connexions as a legal means of delivery.

With regard to cases in which the medical practitioner considers it proper that the facts should be referred to the coroner, it has been the custom of many medical men to refrain from giving a death certificate. Probably this was never in accord with the law, but the point is now made quite clear by the insertion on the back of the death certificate form of a statement, which in an appropriate case the practitioner must initial, stating, for the information of the registrar, that he has reported the case to the coroner. The reporting of a case to the coroner does not justify the omission to give a certificate of the cause of death and to deliver it to the registrar. On receipt of a death certificate endorsed with the statement initialed by the practitioner that he has reported the case to the coroner, it will be the duty of the registrar to suspend the registration of the death until he learns from the coroner whether an inquest is or is not to be held.

MEMBERSHIP of the Guild of St. Luke is open to all students and practitioners of medicine—both men and women—who are members of the Church of England, the clergy of which are eligible as clerical associates. The Guild was started in London by a few medical students, over sixty years ago, and there are also now in London a Women's Ward and a Students' Branch, as well as a Midland Counties Ward and a Cambridge Branch. The Chapter of the Guild meets in each month of the academic year, and a festival service is held annually at St. Luke's tide, either at St. Paul's or Westminster Abbey. This year the service will be at the Abbey. Particulars of the objects and activities of the Guild and forms of application for membership can be obtained from the Secretary of the Guild of St. Luke, Room B B, King's College, Strand, W.C. 2.

THE winter session of the Post Graduate College attached to the West London Hospital reopens on October 3rd, when the dean, Sir Henry Simpson, K.C.V.O., will read a paper on post graduate education in obstetrics. Further information will be found in our advertisement columns.

THE Gilbert Blane medal for this year has been awarded to Surgeon Lieutenant Commander A. W. McKerr, M.B. This medal, founded in memory of Sir Gilbert Blane, is given annually to the medical officer who obtains the highest aggregate marks at the examination for promotion to the rank of surgeon lieutenant commander.

# The British Medical Association:

## ITS AIMS, WORK, AND CONSTITUTION

THE British Medical Association, as stated in our introductory article on the Profession of Medicine, was founded in 1852 to promote the medical and allied sciences, to maintain the honour and interests of the profession, and to foster a feeling of friendship among its members. To its constitution there is added a periodical of meetings for the discussion both of medical and scientific subjects and of professional affairs. It publishes the *British Medical Journal*, it maintains a reference and lending library, it has instituted lectures and scholarships and grants for research. It thus concerns itself with every side of medical work—science, clinical medicine, public health, and the material interests of professional life. The British Medical Association, with a membership now of more than 35,000, is the oldest, largest, and most powerful British organization devoted to the welfare of the medical profession. It has recently acquired a fine building, in Tavistock Square, London, for its headquarters, providing ample accommodation for immediate needs and provision for future development. These new premises, designed by Sir Edwin Lutyens, R.A., were formally opened in 1925 by His Majesty the King, accompanied by the Queen and the beautiful wrought-iron gates erected as a memorial to the 574 members who fell in the war, by which the quadrangle is completed, were dedicated on that occasion by the Archbishop of Canterbury. The need for larger accommodation had become insistent owing to the remarkable growth in the central work of the Association during recent years which had far outstripped the capacity of the premises in the Strand which have now been acquired by the Government of New Zealand for its London offices.

The British Medical Association House, Tavistock Square, London.

### Constitution and Administration

The Association has Branches and Divisions throughout Great Britain and Ireland, and also in the Dominions, Colonies and Dependencies. The Divisions are arranged territorially, and number in all 286. For certain purposes of administration or of scientific and clinical work the Divisions are combined into 93 Branches. Members of Divisions elect representatives on the Branch Councils and also a member or members of the Representative Body, which is the governing body of the Association and determines its policy.

The Council is the executive of the Association. It is elected partly by the Divisions and Branches and partly by the Representative Body, and includes representatives of the Navy, Air Force, Army, and Indian Medical Services elected by the Representative Body. The Representative Body and Council elect standing committees to take charge of different subjects. Among these may be mentioned the Science, Medico-Political, Ethical, Hospitals, Public Health and Naval and Military Committees. There are Committees also for the Dominions, Scotland, Ireland and Wales and for the working machinery of the Association such as the Organization, Finance, and Journal Committees. The Insurance Acts Committee, elected partly by the Association and partly by insurance medical practitioners, is financed by the Association. It is the recognized executive and mouthpiece of the insurance practitioners of Great Britain.

### Privileges of Members

A member of the Association has the right—

- 1 To attend the annual and other general meetings of the Association and the meetings of the Division and Branch to which he or she belongs.
- 2 To take part by personal vote (or in some Divisions by voting paper) in the election of the representative of his or her Division in the Representative Body and also in the election of members of the Council.
- 3 To receive by post the *British Medical Journal*, published weekly, which is a full record with commentary of progress in clinical and scientific medicine and of medico-political affairs throughout the British Empire.
- 4 To receive the help and advice of the central office in any professional difficulty.
- 5 To use the library as a reading room and to borrow current medical or scientific books on payment of postage. Books modern works and periodical medical literature—foreign as well as English—the library contains many books of historic interest.

The full benefits of the Association can only be secured by the co-operation of large numbers of the medical profession, for the greater the membership and the funds the more

efficient and influential the organization. The Association during the past ninety-five years has been the direct means of benefiting every class of medical men and medical women. In asking for new members it looks not only to the older practitioners but also and especially to those recently qualified. To these a generous concession is made as regards subscription, and there is a special claim to their recognition of the work of the Association in improving the conditions under which they may hold appointments in the public service or in civil life. The Association's work for the Service is well known.

It feels a special responsibility towards those members of the profession who by reason of their position are precluded from taking common action and the events of this year have proved again its capacity to further their interests.

### Subscriptions and Applications for Membership

The ordinary subscription to the *British Medical Association* is 3 guineas a year for members resident in the British Isles, but this is subject to various exceptions. Thus, newly qualified practitioners elected within two years of registration pay half this sum up to the end of the fourth year after registration. Medical officers on the active list of the R.N., R.A.F., R.A.M.C. (Regular), and I.M.S. pay 2 guineas. Concessions are made also to members (in the British Isles) of forty years' standing and to members of ten years' standing who have retired from practice to medical married couples residing together, and to whole time teachers and research workers. The ordinary subscription for members living abroad is 1½ guineas, but some Branches have special local subscriptions. A member elected after June 30th pays half the subscription for that year.

All duly qualified British medical practitioners are eligible for election. Full particulars can be obtained from the Medical Secretary, British Medical Association House, Tavistock Square, London, W.C.1, the Scottish Medical Secretary, 6 Drumhugh Gardens, Edinburgh, or the Irish Medical Secretary, 16, South Frederick Street, Dublin.

## Association Notices

### BRANCH AND DIVISION MEETINGS TO BE HELD

**SUSSEX BRANCH BRIGHTON DIVISION**—A clinical meeting of the Brighton Division will be held at the Heritage, Chaley, on the afternoon of Saturday, September 24th. Members are invited to bring their wives, who will be conducted over the Heritage during the meeting. By the kindness of Mrs Kimmins tea will be provided. A detailed programme will be announced later. Members intending to be present are requested to inform the honorary secretary as early as possible, also any members desiring to be taken by car are requested to write to the secretary, as there are plenty of seats available.

### Meetings of Branches and Divisions.

#### CAPE MIDLAND BRANCH

The meeting of the Cape Midland Branch on July 23rd was the first medical gathering ever held in Humansdorp.

Dr HANS GREFF read a paper on bone grafting, which was illustrated by skiagrams. Dr NORMAN WILSON, in a paper on diphtheria, laid special stress on the value of the Schick reaction as an indication of susceptibility or otherwise. A general discussion followed.

Dr HANS GREFF then demonstrated a urethral phosphatic calculus, a piece of articular cartilage which he had removed from the head of the radius, following an injury to the elbow joint, a portion of a stomach which he had excised—the condition was one of ulcer of the lesser curvature. Dr J J COULTON moved a vote of thanks to the readers of the papers and Dr Gordon ROSSON, on behalf of the visiting members, cordially thanked Drs Coulton and Shanks for their hospitality.

A most enjoyable meeting was terminated by the visiting members dining at the Royal Hotel as the guests of Drs Coulton and Shanks.

### VACANCIES

**AIR COUNCIL HOSPITAL**—Senior and Junior House Surgeons (males). Salaries at the rate of £100, and £80 rising to £100, per annum respectively.

**BATH CITY**—Assistant Medical Officer. Salary £600 per annum.

**BATH ROYAL UNITED HOSPITAL**—(1) House Physician. (2) Assistant House Surgeon. Salary £120 and £100 per annum respectively.

**BIRMINGHAM CITY**—Medical Officer of Health. Salary £1800 per annum.

**BIRMINGHAM AND MIDLAND EAR AND THROAT HOSPITAL**—(1) Junior House Surgeon. (2) Third House Surgeon. Non resident. Salary at the rate of £200 per annum each.

**BIRMINGHAM AND MIDLAND EYE HOSPITAL**—Junior House Surgeon. Salary £110 per annum.

**BRISTOL ROYAL INFIRMARY**—Senior Resident Medical Officer. Salary at the rate of £200 per annum.

**CARDIFF CITY MENTAL HOSPITAL, Whitechurch, near Cardiff**—Senior Assistant Medical Officer (male). Salary £550 per annum, rising to £600, or to a married man £700.

**DARLINGTON GENERAL HOSPITAL**—House Surgeon (male). Salary £125 per annum.

**DEPFWSHIRE EDUCATION COMMITTEE**—Assistant School Medical Officer (male). Salary £600 per annum rising to £700.

**HOSPITAL OF ST JOHN AND ST ELIZABETH, Grove End Road, N W 8**—Resident House Physician (male). Salary at the rate of £100 per annum.

**LEFDS PUBLIC DISPENSARY**—Honorary Dental Surgeon.

**LIVERPOOL INSTITUTE OF PREVENTIVE MEDICINE, S W 1**—Research Fellowship in Bacteriology. £500 per annum.

**LONDON FEMALE LOCK HOSPITAL, 203, Harrow Road, W 9**—House Surgeon. Salary at the rate of £150 per annum.

**LONDON HOSPITAL, E 1**—(1) Physician. (2) Surgeon.

**LONDON LOCK HOSPITAL, 91 Dean Street, W 1**—(1) Surgical Registrar. Honorarium £100 per annum. (2) House Surgeon at the Male Lock Hospital. Salary at the rate of £200 per annum.

**LORN MAJOR TRELOAR CRIPPLES HOSPITAL, Alton and Hayling Island**—Assistant Resident Medical Officer (male). Salary £300 per annum.

**MANCHESTER ANCOATS HOSPITAL**—House Surgeon (male). Salary at the rate of £100 per annum.

**MANCHESTER BABIES HOSPITAL**—(1) Resident Medical Officer. (2) Junior Resident Medical Officer. Salaries at the rate of £125 and £50 per annum respectively.

**MANCHESTER ROYAL MANCHESTER CHILDREN'S HOSPITAL, Pendlebury**—(1) Resident Medical and Surgical Officers (unmarried). Salary £125 per annum. (2) Two Assistant Medical Officers (non resident) for Out patients Department, Garfield Street. Salary £150 per annum.

**NATIONAL HOSPITAL FOR DISEASES OF THE HEART, Westmoreland Street, W 1**—(1) Resident Medical Officer. (2) Outpatient Medical Officer (non resident). Males. Salary at the rate of £150 and £125 per annum respectively.

**NEWCASTLE ON TYNE ROYAL VICTORIA INFIRMARY**—Resident Medical Officer (male). Salary £360 per annum, rising to £350.

**NORTHAMPTON GENERAL HOSPITAL**—Two House Surgeons. Salary at the rate of £150 per annum each.

**NOTTINGHAM GENERAL DISPENSARY**—Resident Surgeon (male). Salary £250 rising to £300.

**OXFORD RADCLIFFE INFIRMARY AND COUNTY HOSPITAL**—(1) House Physician. (2) Casualty House Surgeon. Salary at the rate of £120 per annum each.

**PRESTON AND COUNTY OF LANCASTER ROYAL INFIRMARY**—House Physician. Salary £190 per annum.

**QUEEN'S HOSPITAL FOR CHILDREN, Hackney Road, E 2**—House Surgeon. Salary at the rate of £100 per annum.

**ROYAL GWENT HOSPITAL, Newport, Mon**—House Surgeon. Salary at the rate of £125 per annum.

**ROYAL NATIONAL ORTHOPAEDIC HOSPITAL, Great Portland Street, W 1**—House Surgeon. Salary £150 a year.

**ST PETER'S HOSPITAL FOR STONE ETC, Henrietta Street, W C 2**—House Surgeon. Salary at the rate of £75 per annum.

**SUMMITTAN FREE HOSPITAL FOR WOMEN, Marblebone Road, N W**—Anaesthetist, twice weekly. Honorarium £30 per annum.

**SLAMEN'S HOSPITAL SOCIETY**—(1) House Physician at the Hospital for Tropical Diseases Endsleigh Gardens, W C (male). (2) House Physician and House Surgeon at the Dreadnought Hospital Greenwich. (3) House Surgeon at the Albert Dock Hospital. Salary at the rate of £110 per annum each.

**SHEFFIELD ROYAL HOSPITAL**—Resident Anaesthetist (male). Salary £83 per annum.

**STAFFORDSHIRE EDUCATION COMMITTEE**—Assistant School Medical Inspector (male). Salary £600, rising to £800.

**TUNBRIDGE WELLS EYE AND EAR HOSPITAL**—House Surgeon (male). Salary £150 per annum.

**WARRINGTON INFIRMARY AND DISPENSARY**—Senior House Surgeon (male). Salary £250 per annum.

**WEST LONDON HOSPITAL, Hammersmith Road, W 6**—(1) House Physician. (2) Two House Surgeons (males). Salary at the rate of £100 per annum.

**WILDESDEN GENERAL HOSPITAL, Harlesden Road, N W 10**—Chemical Assistant to the Outpatient Medical Department.

**WOLFRHAMPTON AND MIDLAND COUNTIES EYE INFIRMARY**—House Surgeon. Salary £200 per annum.

**CERTIFYING FACTORY SURGEONS**—The following vacant appointments are announced: Stamford (Lincoln) and Llanelly (Carmarthen). Applications to the Chief Inspector of Factories Home Office Whitehall S W 1.

**MEDICAL REFEREE UNDER THE WORKMEN'S COMPENSATION ACT 1925** for Districts of Chepstow, Newport, and Pontypool County Courts (Circuit No 24). Applications to the Private Secretary, Home Office, Whitehall, S W, by September 17th.

This list of vacancies is compiled from our advertisement columns where full particulars will be found. To ensure notice in this column advertisements must be received not later than the first post on Tuesday morning.

### APPOINTMENTS

**BURRILL JONES, H S L S A L M S S A, D P H O xon**, Registrar at the Ear and Throat Hospital, Golden Square.

**CHILL, Lieut Colonel R J, D S O M B, B Ch**, additional Medical Referee under the Workmen's Compensation Act, 1925, for the Districts of the Chester, and Nantwich and Crewe County Courts (Circuit No 7).

**HENNESSY, Robert F M B, B Ch**, House Surgeon at the Armagh County Infirmary.

**JONES, Norman A, F R C S**, Surgeon to the Ear, Nose, and Throat Department of the Royal Northern Hospital, Holloway Road, London.

### British Medical Association OFFICES, BRITISH MEDICAL ASSOCIATION HOUSE, TAVISTOCK SQUARE W C 1

#### Departments

**SUBSCRIPTIONS AND ADVERTISEMENTS** (Financial Secretary and Business Manager: Telegrams Articulate Westcent London).

**ADMINISTRATIVE SECRETARY** (Telegrams Mediscera Westcent London).

**EDITOR, British Medical Journal** (Telegrams Vitalogy Westcent London).

Telephone numbers of British Medical Association and British Medical Journal Museum 9951 9952 4603 and 4654 (internal exchange four lines).

**SCOTTISH MEDICAL SECRETARY** 6 Drumshengh Gardens Edinburgh (Telegrams Associate Edinburgh Tel 461 Central).

**IRISH MEDICAL SECRETARY** 16, South Frederick Street Dublin (Telegrams Baecillus, Dublin Tel 4737 Dublin).

#### Diary of the Association

**SEPTEMBER**

13 Tues	London	Central Ethical Committee 2 p.m.
15 Thurs	London	Insurance Acts Committee, 12 noon
16 Fri	London	Public Health Committee, 2.30 p.m.
20 Tues	London	Organization Committee
21 Wed	London	Medical Political Committee, 2.30 p.m.
22 Thurs	London	Journal Committee, 2.30 p.m.
24 Sat	Brighton	Division Clinical Afternoon The Heritage, Chaley
27 Tues	London	Hospitals Committee, 2.30 p.m.
28 Wed	London	Finance Committee 2.30 p.m.

**OCTOBER**

5 Wed London Arrangements Committee Meeting of Council Members, 11 a.m. Full Committee, with the Cardiff Members, 2.30 p.m.

### BIRTHS, MARRIAGES, AND DEATHS

The charge for inserting announcement of Births, Marriages, and Deaths is 9s., which sum should be forwarded with the notice not later than the first post on Tuesday morning, in order to ensure insertion in the current issue.

#### BIRTHS

**LUTHERLAND**—At Milton Lodge, Wigan, on August 28th to Dr Doris Lutherland (née Knowles) wife of Dr Henry Lutherland a son.

**McROBERT**—At Maymyo, Upper Burma on August 23rd to the wife of Captain Ronald McRobert, I.M.S., a daughter.

**WEBSTER**—At Baroda, India on August 7th, 1927, to Janet wife of Captain W J Webster, Indian Medical Service, a daughter.

#### MARRIAGES

**GILLIES-PREECE**—At St Paul's, Porth Rhondda on August 25th Dugald Richard, M.B., Ch.B. St Andrews son of the late Hugh Gillies, J.P., to Hilda Mary, youngest daughter of John Preece, Mnesyrth, Porth.

**ROSS-WRAY**—At Kisumu, Kenya Colony, on July 20th by the Rev. H. Hitchen, Percy Ross, M.B., Ch.B. Aberd. younger son of Mr. A. I. Mrs. J. Ross, Brora, Scotland, to Mercia Anne, eldest daughter of Mr. and Mrs. R. W. Wray, Tamarama Bay, Sydney, Australia.

#### DEATHS

**DRURY**—At Landon House, Halifax, Yorkshire, on August 22nd Arthur Drury, M.B., Ch.M. Ed., aged 65 years.

**ELLIOTT**—Suddenly at 113, Grove Road, Waltham town, on August 25, Frank Percy Elliott M.B., Ch.M., aged 57 years.

[The present issue being the Annual Educational Number, much current material is held over, and neither the "Supplement" nor the "Epitome of Current Medical Literature" is published this week.]

# An Address ON DARWIN'S THEORY OF MAN'S DESCENT AS IT STANDS TO-DAY

DELIVERED TO THE BRITISH ASSOCIATION\*  
BY THE PRESIDENT,

PROFESSOR SIR ARTHUR KILPIN, M.D., F.R.S.,  
CONSERVATOR OF THE MUSEUM OF THE ROYAL COLLEGE OF  
SURGEONS OF ENGLAND

IN tracing the course of events which led up to our present conception of Man's origin, no place could serve as a historical starting-point so well as Leeds. In this city was fired the first verbal shot of that long and bitter strife which ended in the overthrow of those who defended the Biblical account of Man's creation and in a victory for Darwin. When the British Association assembled in this city in 1858 Sir Richard Owen, the first anatomist of his age, was its president. In a long address he reviewed the whole realm of Science. During its course he cited evidence which suggested a much earlier date for the appearance of Man on earth than was sanctioned by Biblical records, but poured scorn on the idea that Man was merely a transmuted ape. He declared that the differences between Man and ape were so great that it was necessary to assign mankind to an altogether separate Order in the animal kingdom. As this statement fell from the President's lips there was at least one man in the audience who a spirit of opposition was roused—Thomas Henry Huxley—Owen's young and rising antagonist. I have picked out Huxley because it is necessary, for the development of my theme, that we should give him our attention for a moment. The Leeds meeting passed off amicably, but two years later in 1860, when this Association met in Oxford, Owen in the course of a discussion, repeated the statement made at Leeds as to Man's separate position, claiming that the human brain had certain structural features never seen in the brain of anthropoid apes. Huxley's reply was a brief and emphatic denial, with a promise to produce evidence in due course—which was faithfully kept. This opening passage of arms was followed two days later by that spectacular fight in which the Bishop of Oxford, the representative of Owen and of Orthodoxy, left his scalp in Huxley's hands. To make his victory decisive and abiding Huxley published, early in 1863 *The Evidence of Man's Place in Nature*, a book which settled for all time that Man's rightful position is among the primates, and that as we anatomists weigh evidence, his nearest living kin are the anthropoid apes.

My aim is to make clear the foundations on which rest our present-day conception of Man's origin, but I must turn to another issue, which, though it was merely touched upon by Sir Richard Owen, is of supreme interest to us now. Earlier in that year Sir Charles Lyell and Sir Joseph Hooker left with the Linnean Society what appeared to be an ordinary roll of manuscript, but what in reality was a parcel charged with high explosives, prepared by two very innocent-looking men—Alfred Russel Wallace and Charles Darwin. It must be admitted that these two men were well aware of the deadly nature of its contents, but Owen examined them and came to the conclusion that they were not dangerous, at least, he manifested no sign of alarm in his Presidential Address.

## *The Transformation of our Outlook on Man's Origin*

I cannot help marvelling over the difference of outlook between my audience and that which Sir Richard Owen had in this city sixty-nine years ago. The vast assemblage which confronted him was convinced almost without a dissentient that Man had appeared on earth by a special act of creation, the audience I address, and that larger congregation which the wonders of wireless bring within the reach of my voice if not convinced Darwinists are yet

prepared to believe, when full proofs are forthcoming that Man began his career as a humble primate animal, and has reached his present estate by the action and reaction of biological forces which have been and are ever at work within his body and brain.

## *Darwin's Generalship*

This transformation of outlook on Man's origin is one of the marvels of the nineteenth century, and to see how it was effected we must turn our attention for a little while to the village of Down in the Kentish uplands and note what Charles Darwin was doing on the very day that Sir Richard Owen was delivering his address. He sat in his study struggling with the first chapter of a new book but no one for a moment, Owen least of all, that the publication of the completed book, *The Origin of Species*, fifteen months later (1859), was to effect a sweeping revolution in our way of looking at living things and to initiate a new period in human thought—the Darwinian Period—in which we still are. Without knowing it Darwin was a consummate general. He did not launch his first campaign until he had spent twenty-two years in stocking his arsenal with ample stores of tested and assorted facts. Having won territory with *The Origin of Species* he set to work to consolidate his gains by the publication in 1868 of another book, *The Variation of Animals and Plants under Domestication*—a great and valuable treasury of biological observation. Having thus established an advanced base, he moved forwards on his final objective—the problem of human beginnings—by the publication of *The Descent of Man* (1871), and that citadel capitulated to him. To make victory doubly certain he issued in the following year—1872—*The Expression of the Emotions in Man and Animals*. Man a soldier of truth had attempted this citadel before Darwin's day, but they failed because they had neither his generalship nor his artillery.

## *History as Written by Darwin*

Will Darwin's victory endure? Before attempting to answer this question, let us look at what kind of book *The Descent of Man* is. It is a book of history—the history of Man, written in a new way—the way discovered by Charles Darwin. I will illustrate the Darwinian way of writing history. If a history of the modern bicycle had to be written in the orthodox way, we should search dated records until every stage was found which linked the two-wheeled hobby horse, bestrode by tall hatted men at the beginning of the nineteenth century, to the modern "jeopardy" which now flashes past us in country lanes. But suppose there were no dated records—only a jumble of antiquated machines stored in the cellar of a museum. We should then have to adopt Darwin's way of writing history. By an exact and systematic comparison of one machine with another we could infer the relationship of one to another and tell the order of their appearance, but as to the date at which each type appeared and the length of time it remained in fashion we could say very little. It was by adopting this circumstantial method that Darwin succeeded in writing the history of Man. He gathered historical documents from the body and behaviour of Man and compared them with observations made on the body and behaviour of every animal which showed the least resemblance to Man. He studied all that was known in his day of Man's embryological history and noted resemblances and differences in the corresponding histories of other animals. He took into consideration the manner in which the living tissues of Man react to disease, to drugs, and to environment, he had to account for the existence of diverse races of mankind. By a logical analysis of his facts Darwin reconstructed the history of Man.

## *Darwin's Position has become Impregnable*

Fifty-six years have come and gone since that history was written, an enormous body of new evidence has poured in upon us. We are now able to fill in many pages which Darwin had to leave blank and we have found it necessary to alter details in his narrative, but the fundamentals of Darwin's outline of Man's history remain unshaken. Nay, so strong has his position become that I am convinced that it never can be shaken.

\*The address has been slightly shortened by the omission of a few sentences. (See also page 438)

*The Evidence of Fossil Remains*

I say confidently that Darwin's position has become impregnable because since his death in 1882 we have succeeded in tracing Man by means of his fossil remains and by his stone implements backwards to the very beginning of that period of the earth's history to which the name Pleistocene is given. We thus reach a point in history which is distant from us at least 200,000 years, perhaps three times that amount. Nay, we have gone further, and traced him into the older and longer period which preceded the Pleistocene—the Pliocene. It was in this period that a stream in Java during the later part of the Pliocene period that Dr. Eugen Dubois found, ten years after Darwin's death, the fossil remains of that remarkable representative of primitive humanity to which he gave the name *Pithecanthropus*, or Ape-man, from Pliocene deposits of East Anglia Mr. Reid Moss has recovered rude stone implements. If Darwin was right, then as we trace Man backwards in the scale of time he should have become more bestial in form—nearer to the ape. That is what we have found. But if we regard *Pithecanthropus* with his small and simple human brain as a fair representative of the men of the Pliocene period, then evolution must have proceeded at an unexpectedly rapid rate to culminate to-day in the higher races of mankind.

*Man's Descent has not been in a Straight Line*

The evidence of Man's evolution from an ape-like being, obtained from a study of fossil remains, is definite and irrefutable, but the process has been infinitely more complex than was suspected in Darwin's time. Our older and discarded conception of Man's transformation was depicted in a well known diagram which showed a single file of skeletons, the gibbon at one end and Man at the other. In our original simplicity we expected, as we traced Man backwards in time, that we should encounter a graded series of fossil forms which would carry him along a straight path to an anthropoid ancestor. We should not have made this fatal mistake if we had remembered that the guide to the world of the past is the world of the present. In our time Man is represented not by one but by many and diverse races—black, brown, yellow and white, some of these are rapidly expanding, others are as rapidly disappearing. Our searches have shown that in remote times the world was peopled, sparsely it is true, with races showing even a greater diversity than those of to-day, and that even then the same process of replacement was at work. We have to thread our way, not along the links of a chain, but amongst the meshes of a complicated network.

*Diversity of Form in Ancient Times*

We committed a still further blunder. Seeing that in our search for Man's ancestry we expected to reach an age when the beings we would have to deal with would be human rather than human, we ought to have marked the conditions which prevail amongst living anthropoid apes. We ought to have been prepared to find, as we approached a distant point in the geological horizon, that the forms encountered would be as widely different as are the gorilla, chimpanzee, and orang, and confined as these great anthropoids now are, to limited parts of the earth's surface. That is what we are now realizing, as we go backwards in time we discover that mankind becomes broken up, not into separate races as in the world of to-day, but into numerous and separate species. When we go into a still more remote past they become so unlike that we have to regard them not as belonging to separate species but different genera. It is amongst this welter of extinct fossil forms which strew the ancient world that we have to trace the zigzag line of Man's descent.

*Discordant Evolution*

We made another mistake when we set out on the search for Man's ancestry, indeed, some of us are still making it. We expected that Man's evolution would pursue not only an orderly file of stages, but that every part of his body—skull, brain, jaws, teeth, skin, body, arms, and legs—would at each stage become a little less ape-like, a little more Man-like. Our searches have shown us that Man's evolu-

tion has not proceeded in this manner. In some extinct races, while one part of the body has moved forward, another part has lagged behind. We now know that, as Darwin sat in his study at Down, there lay hidden at Piltdown, in Sussex, not thirty miles distant from him, sealed up in a bed of gravel, a fossil human skull and jaw. In 1912, thirty years after Darwin's death, Mr. Charles Dawson discovered this skull, and my friend Sir Arthur Smith Woodward described it, and rightly recognized that skull and jaw were parts of the same individual, and that this individual had lived, as was determined by geological and other evidence, in the opening phase of the Pleistocene period. We may confidently presume that this individual was representative of the people who inhabited England at this remote date. The skull, although deeply mouldered and thick-walled, might well have been the rude forerunner of a modern skull, but the lower jaw was so ape-like that some experts denied that it went with the human fossil skull at all, and supposed it to be the lower jaw of some extinct kind of chimpanzee. This mistake would never have been made if those concerned had studied the comparative anatomy of anthropoid apes, for then they would have been prepared to meet with the discordances of evolution. The same irregularity in the progression of parts is evident in the anatomy of *Pithecanthropus*, the oldest and most primitive form of humanity so far discovered. The thigh-bone might easily be that of modern man, the skull cap that of an ape, but the brain within that cap, as we now know, had passed well beyond an anthropoid status. If merely a lower jaw had been found at Piltdown in ancient Englishman would have been wrongly labelled "Higher anthropoid ape" if only the thigh-bone of *Pithecanthropus* had come to light in Java, then an ancient Javanese, almost deserving the title of anthropoid, would have passed muster as a man.

*Man's Still Remain in the Geological Record*

Such examples illustrate the difficulties which beset the task of unravelling Man's ancestry, and there are others, there still remain great blanks in the geological record of Man's evolution, as our search proceeds these blanks will be filled in. By the discovery of fossil remains we have followed Man backwards to the close of the Pliocene period, which endured at least for a quarter of a million years, but we have not yet succeeded in tracing him through this period. It is true that we have found fossil teeth in Pliocene deposits which may be those of an ape-like man or of a man-like ape until we find other parts of their bodies we cannot tell. When we pass into the still older Miocene period—one which was certainly twice as long as the Pliocene—we are in the heyday of anthropoid history. Thanks to the labours of Dr. Guy E. Pilgrim, of the Indian Geological Survey, we know already of a dozen different kinds of great anthropoids which lived in Himalayan jungles during middle and later Miocene times, we know of at least three other kinds of great anthropoid apes which lived in the contemporary jungles of Europe. Unfortunately we have found as yet only the most resistant parts of their bodies—teeth and fragments of jaw. Do some of these fragments represent an ancestor of man? We cannot decide until a lucky chance brings to light a limb-bone or a piece of skull, but no one can compare the teeth of these Miocene anthropoids with those of primitive man, as has been done so thoroughly by Professor William K. Gregory, and escape the conviction that in the dentitions of the extinct anthropoids of the Miocene jungles we have the ancestral forms of human teeth.

*Date of Man's Emergence*

It is useless to go to still older than the Miocene in search of Man's emergence, in such strata we have found only fossil traces of emerging anthropoids. All the evidence now at our disposal supports the conclusion that Man has arisen, as Lamarck and Darwin suspected, from an anthropoid ape not higher in the zoological scale than a chimpanzee, and that the date at which human and anthropoid lines of descent began to diverge lies near the beginning of the Miocene period. On our modest scale of reckoning that gives Man the respectable antiquity of about one million years.

*Proofs of Our Anthropoid Inheritance*

Our geological search has not produced so far the final and conclusive evidence of Man's anthropoid origin, we have not found as yet the human *homo* emerging from its anthropoid environment. Why then do modern anthropologists share the conviction that there has been an anthropoid stage in our ancestry? They are not blind to the degree of difference which separates Man and ape in structure in appearance and in behaviour. I must touch on the sources of this conviction only in a passing manner. Early in the present century Professor C. H. D. Atchall of Cambridge University discovered a trustworthy and exact method of determining the affinity of one species of animal to another by comparing the reaction of their blood. He found that the blood of Man and that of the great anthropoid apes gave almost the same reaction. That biologists find that the living anthropoid body possesses almost the same susceptibilities to infections and transmits the same reaction, as does the body of Man. So also are the brains of Man and anthropoid in their structural organization that surface and physiological traits for experimental observation pass from the one to the other. When the human embryo is fully formed in the womb it throws out structures of a most complex nature to effect a connexion with the maternal body. We now know that exactly the same elaborate processes occur in the anthropoid world and in no other. We find the same vascular structure—the same evolutionary pattern—in the bodies of Man and anthropoid. The anthropoid mother fondles, nurses and suckles her young in the human manner. This last is a title of the striking and intimate points in which Man resembles the anthropoid ape. In what other way can such a myriad of coincidences be explained except by presuming a common ancestry for both.

*The Evolution of Man's Brain*

The crucial chapters in Darwin's *Descent of Man* are those in which he seeks to give an historical account of the rise of Man's brain and of the varied functions it subserves. Darwin was not a professional anatomist and therefore accepted Huxley's statement that there was no structure in the human brain that was not already present in that of the anthropoid. In Huxley's opinion the human brain was but a richly annotated edition of the simpler and older anthropoid book and that this edition in turn was but the expanded issue of the still older original primate publication. Since this statement was made thousands of anatomists and physiologists have studied and compared the brain of Man and ape, only a few months ago Professor G. Elliot Smith summarized the result of this intensive inquiry as follows:

No structure found in the brain of an ape is lacking in the human brain and on the other hand the human brain reveals no formation of any sort that is not present in the brain of the gorilla or chimpanzee. The only distinctive feature of the human brain is a quantitative one.

Though the difference is only quantitative its importance cannot be exaggerated. In the anthropoid brain are to be recognized all the parts which have become so enormous in the human brain. It is just these expansions which have given Man his powers of feeling, understanding, acting, speaking and learning.

*The Evidence of Psychology*

Darwin himself approached this problem not as an anatomist but as a psychologist and after many years of painstaking and exact observation convinced himself that,

immeasurable as are the differences between the mentality of Man and ape, they are of degree not of kind. Prolonged researches made by modern psychologists have verified and extended Darwin's conclusions. No matter what line of evidence we select to follow—evidence gathered by anatomists, by embryologists, by physiologists or by psychologists—we reach the conviction that Man's brain has been evolved from that of an anthropoid ape and that in the process no new structure has been introduced and no new or strange faculty interpolated.

*Unexplained Problems*

But hardly is it in sight, our inquiries are but begun. Will the day ever come when we can explain why the brain of man has made such great progress while that of his cousin the gorilla has fallen so far behind? Can we explain why inherited ability falls to one family and not to another or why in the matter of cerebral endowment one race of mankind has fared so much better than another? We have as yet no explanation to offer but an observation in half a century ago by one on whom Nature has not rested her gifts—the former President of this Association and the doyen of British science, Sir J. Payk, I make the following quotation on this connection:

The leading feature in the development of Man from other animals is undoubtably the relative enormous size of the brain in Man and the corresponding increase in its activities and capacities. It is a striking fact that it was not in the ancestors of Man alone that this increase in the size of the brain took place at the same period—the Miocene. Other great mammals of the early Tertiary period were in the same case.

When primates made their first appearance in the geological record they were one and all small brained.

*Darwin's Conception of Evolution Illustrated*

I have spoken of Darwin as an historian. I did so because events and to give the order of their occurrence is the essential part of an historian's task, his most difficult, begin when he seeks to interpret the happenings of history and detect the causes which produced them. Up to this point I have been considering only the materials for Man's history, and placing them so far as our scanty

information allows in the order of their sequence, but now we have to select out the biological processes and controlling influences which have shaped the evolutionary histories of Man and ape. It will repay us to use the evolution of new types of motor cars as an illustration. In the evolution of motor vehicles Darwin's law of Selection has prevailed: there has been severe competition and the types which have answered best to the needs and tastes of the public have survived. The public has selected on two grounds—first for utility thus illustrating Darwin's law of Natural Selection—and secondly because of appearance's sake for as most people know a new car has to satisfy not only the utilitarian demands of its prospective master but also the æsthetic tastes of its prospective mistress, thereby illustrating Darwin's second law—the law of Sexual Selection. The public has selected types of car but it has had no direct hand in designing and producing modifications and improvements which have appeared year after year. To understand how such modifications are produced the inquirer must enter a factory and not only watch artisans shaping and fitting parts together but also visit the designer's office. In this way he will obtain a glimpse of the evolution of motor cars. If we are to understand the machinery which underlies the evolution of Man and of ape, we have to enter the "factories" where they are

This diagram illustrates the relation between the brain size of various primates over geological time. It is based on the data provided in the text, showing the progression of brain size from 2,000 MYA to 500 MYA for three different groups of primates.

produced—look within the womb and see the ovum being transformed into an embryo, the embryo into a foetus, and the foetus into a babe. After birth we may note infancy passing into childhood, childhood into adolescence, adolescence into maturity, and maturity into old age. Merely to register the stages of change is not enough, to understand the controlling machinery we have to search out and uncover the processes which are at work within developing and growing things and the influences which co-ordinate and control all the processes of development and of growth. When we have discovered the machinery of development and of growth we shall also know the machinery of Evolution, for they are the same.

If the simile I have used would have sounded strange in Darwin's ear, the underlying meaning would have been familiar to him. Over and over again he declared that he did not know how "variations" were produced, favourable or otherwise, nor could he have known, for in his time hormones were undreamed of and experimental embryology scarcely born. With these recent discoveries new vistas opened for students of Evolution. When we compare the evolutionary machinery in a motor factory with that which regulates the development of an embryo within the womb, we realize how different the two processes are. Let us imagine for a moment what changes would be necessary were we to introduce "embryological processes" into a car factory. We have to conceive a workshop teeming with clustering swarms of microscopic artisans, mere specks of living matter. As we pass along we note that every part of a car is in process of manufacture, each part being the business of a particular brigade of microscopic workmen. There is no apprenticeship in this factory, every employee is born, just as a hive-bee is, with his skill already fully developed. No plans or patterns are supplied, every workman has the needed design in his head from birth. There is neither manager, overseer, nor foreman to direct and co-ordinate the activities of the vast artisan armies. And yet if parts are to fit when assembled, if pinions are to mesh and engines run smoothly, there must be some method of co-ordination. It has to be a method plastic enough to permit difficulties to be overcome and the introduction of advantageous modifications when these are needed. A modern works manager would be hard put to it were he asked to devise an automatic system of control for such a factory, yet it is just such a system that we are now obtaining glimpses of in Nature's living workshops.

#### *The Machinery of Development and Growth*

I have employed a crude simile to give an inkling of what happens in that factory where the most complicated of machines are forged—the human body and brain. The fertilized ovum divides and redivides, one brood of microscopic living units succeeds another, and as each is produced the units group themselves to form the "parts" of an embryo. Each "part" is a living society, the embryo is a huge congeries of interdependent societies. How are their respective needs regulated, their freedoms protected, and their activities timed? Experimental embryologists have begun to explore and discover the machinery of regulation. We know enough to realize that it will take many generations of investigators to work over the great and new field which is thus opening. When this is done we shall be in a better position to discuss the cause of "variation" and the machinery of Evolution.

If we know only a little concerning the system of government which prevails in the developing embryo we can claim that the system which prevails in the growing body, as it passes from infancy to maturity, is becoming better known every year. The influence of the sex glands on the growth of the body has been known since ancient times, their removal in youth leads to a transformation in the growth of every part of the body, altering at the same time the reactions and temperament of the brain. In more recent years it has been observed that characteristic alterations in the appearance and constitution of the human body can be produced by the action of other glands—the pituitary, thyroid, parathyroid, and adrenals. Under the disorderly action of one or other of these glands individuals may, in the course of a few years, become so changed in appearance that the differences between them

and their fellows become as great as, or even greater than, those which separate one race of mankind from another. The physical characters which are thus altered are just those which mark one race off from another. How such effects are produced we did not know until 1904, when the late Professor E. H. Starling, a leader amongst the great physiologists of our time, laid bare in ancient and fundamental law in the living animal body—his law of hormones. I have pictured the body of a growing child as an immense society made up of myriads of microscopic living units, ever increasing in numbers. One of the ways—probably the oldest and most important way—by which the activities of the communities of the body are co-ordinated and regulated is by the postal system discovered by Starling, wherein the messengers are hormones—chemical substances in ultra-microscopic amounts, dispatched from one community to another in the circulating blood. Clearly the discovery of this ancient and intricate system opens up fresh vistas to the student of Man's evolution. How Darwin would have welcomed this discovery! It would have given him a rational explanation to so many of his unsolved puzzles, including that of "correlated variations." Nor can I in this connexion forbear to mention the name of one who presided so ably over the affairs of this Association fifteen years ago—Sir E. Sharpey-Schiff. He was the pioneer who opened up this field of investigation and has done more than anyone to place our knowledge of the nature and action of the glands of internal secretion on a precise basis of experimental observation. With such sources of knowledge being ever extended and others of great importance, such as the study of heredity, which I have left unmentioned, we are justified in the hope that Man will be able in due time not only to write his own history but to explain how and why events took the course they did.

I have attempted to answer a question of momentous importance—What is Man's origin? Was Darwin right when he said that Man, under the action of biological forces which can be observed and measured, has been raised from a place amongst anthropoid apes to that which he now occupies? The answer is Yes! and in returning this verdict I speak but as foreman of the jury—a jury which has been empanelled from men who have devoted a lifetime to weighing the evidence. To the best of my ability I have avoided, in stating the evidence on which our verdict was found, the role of special pleading, being content to follow Darwin's own example—Let the Truth speak for itself.

## DISCUSSION ON THE HYGIENE OF MENSTRUATION IN ADOLESCENTS

### I—DEVELOPMENTAL CHANGES DURING ADOLESCENCE

BY

R. W. JOHNSTONE, C.B.E., M.D., F.R.C.S. Ed.,  
Professor of Midwifery and the Diseases of Women,  
University of Edinburgh

I WELCOME the opportunity of opening this discussion on the hygiene of menstruation in adolescents. The subject is a most important one and, as it is a matter which falls peculiarly within the province of the confidential family physician, there could be no more suitable gathering than this in which to discuss it. Few matters in regard to feminine hygiene have a more profoundly far-reaching importance. The wise management of a girl's life at the period of adolescence gives the functions of her reproductive organs a good start, and if these behave normally to begin with there is the more likelihood that they will continue to do so. The converse is equally but not more true, although it is much more frequently brought to our

\* Report of a discussion in the Section of Obstetrics and Gynaecology at the Annual Meeting of the British Medical Association at Edinburgh. Dr J. Haig Ferguson, President of the Section, was in the chair.

professional notice—namely, that mismanagement of a girl's health at this time only too often spells suffering, unhappiness and disappointment which may throw a shadow over her whole subsequent life.

In our present purpose the period of adolescence which is variously defined by different writers may be taken to extend from the time when the changes of puberty begin to that time when the function of menstruation has become regularly established. The secondary sex characters have become fully developed and the girl has practically reached her full physical stature. Generally speaking, this phase extends in the girls of our own race to about 12½ to 17 or 18 years, varying within limits in each individual. The change occurring in the anatomy and physiology of the body during the years are the most important of the whole life time. The almost sexual child begins to develop definitely and rapidly for all more and more complete femininity. The anatomical changes pass from the angular awkward tomboy to the rounded girl with her soft rounded curves and graceful dignity of a woman. The change is familiar to all. The psychological change is no less familiar with its characteristic increase in nobility and reserve and a tendency to romanticism. A whole new world of thought and emotion is opening up before the girl's mind during this period and if her emotional nature is apt to be a little unstable at this time it is scarcely to be wondered at. The underlying physiological changes are even more profound and of them the most obvious and arresting is the beginning of the menstrual function.

It is no part of my intention to examine these changes in detail but it is essential to emphasize that the development from bud to flower takes time and that even the regular establishment of menstruation does not of itself indicate anything like complete physiological or anatomical maturity. The bony pelvis, for example, probably does not reach its full size and width until about 22 or 23 years, when the young woman may be said to have reached the age of nubility and can with safety become a mother. Long before this however the external and internal organs of generation have acquired their adult character and functions and maternity is possible. The uterus, tubes and vagina have lost their infantile size and shape, and developed to more mature proportion. The ovaries have likewise increased in size and the regular ripening of follicles, the discharge of ova, and the subsequent development of corpora lutea have begun. Along with these changes there are other more or less physiological changes such as alterations in the blood and lymph balance and in the biochemistry of the body which I am not competent to discuss. But the great point which we require to keep ever before us is that the girl's entire organism is concerned in the changes of puberty and adolescence. The old belief that the development of the secondary sex characters was due wholly to the internal secretions of the ovaries, has had to be modified as a result of modern research and we now have reason to believe that all the glands of internal secretion are concerned in the process. It is on account of "the totality of her internal secretions"—to use Blair Bell's words—that a woman becomes what she is and even this dictum we must not preface with the impetus towards femininity given at the moment of conception by the fertilization of the ovum by a particular variety of spermatozoon. The periodic premenstrual enlargement of the thyroid is perhaps the only one of the changes in the endocrine glands which is easily observable but the very fact that the changes in the other ductless gland are going on behind the scenes as it were must put us on our guard against any failure to take them into account. It is obvious therefore, that puberty and early adolescence must form a critical period when unhygienic methods of living may easily produce disastrous results affecting both body and mind.

It is not necessary to enter with any fullness upon the complex subject of the actual cause of menstruation. Suffice it to say that the best supported modern view—admittedly incomplete in many details—indicates that it is due to an internal secretion of the ovary, probably of the corpus luteum, but that the ovary cannot function normally unless its functions are harmoniously related to those

of the other members of the endocrine system particularly the thyroid and pituitary glands. Ovation, occurring about a fortnight after the beginning of a menstrual period is followed by the preparation of the endometrium for the nidation of a fertilized ovum. If this is not forthcoming the corpus luteum begins to degenerate and the menstrual decidual as the endometrium at this stage may be described disintegrates with consequent haemorrhage into the uterine cavity and so to the exterior. Regeneration of the uterine mucosa then occurs and in due course the whole of this process is regularly repeated until ultimately fertilization of an ovum occurs when the full sex cycle accomplishes itself in the phenomena of pregnancy, parturition, the puerperium and the period of lactation.

But to return to the phase of adolescence there is no doubt that although the development of the reproductive organ and the commencement of their functioning are accompanied by the manifold physiological changes to which I have referred yet the reproductive organs themselves are the star performers in the drama of puberty and the parts taken by the other organs are subordinated to the full working out of their destiny. Despite any arguments to the contrary reproduction is the greatest function of womanhood, and certainly it is the only one in which Mother Nature takes any special interest. She is almost obsessed with the one idea—reproduction of the species; she has no interest in intellectual developments and indeed where these are extreme she not infrequently makes the individual pay dearly for them. In other words the reproductive organs during this phase of life call for a specially good supply of healthy blood and nerve energy and if these are diverted to any great extent, either to the muscular system or to the intellectual centres, the proper development and early functioning of the reproductive organs are liable to suffer. This is I believe, in its simplest terms the explanation of many of the disorders of menstruation and the reproductive functions which we meet with—amenorrhoea, menorrhagia, dysmenorrhoea and in later life sterility.

While there is then no doubt that puberty and adolescence form one of the critical periods of a woman's life, yet the changes which occur during it and the function of menstruation with which we are particularly concerned are all perfectly natural phenomena. A natural mode of life is accordingly the ideal to be aimed at and since we cannot prescribe a return to nature in the strict sense I would interpret a natural life in terms of our civilization as one that is characterized by "moderation in all things" and one that avoids extremes in any direction. Too strenuous or laborious a life, too much physical or too much brain work, too frivolous an existence or one that is seriously irregular in any respect may do irreparable harm to the girl as regards her reproductive functions.

But almost as much damage alike to the reproductive functions and to the nervous system and the girl's whole mental outlook may be brought about by so treating her that she grows up with the idea that she is a subject of a very special physical delicacy at these periods. This tendency to regard the menstrual function as one of really unnatural delicacy is a relic of the past and to understand it we must look backwards for a moment. It is only within the last thirty years or so that the function of menstruation has been studied in anything like a scientific way. Previous to that time it was of all the obvious physiological functions of the human body perhaps the least understood. From time immemorial it has been considered to be a function imbued with mystery and it was always regarded in the earlier days with an interest which was respectful and frequently not devoid of fear. This element of mystery has had great practical significance because not only did it on the one hand prevent any intelligent study of the function but on the other hand, it fostered the growth of an enormous volume of superstition and baseless speculation round it. Researches into the folk lore of all nations and tongues show that this feeling was universal.

Time does not permit that I should dwell on the erroneous and often fantastic views that have been held concerning menstruation, but a very brief reference to this

aspect of the matter is essential. From prehistoric days the function of menstruation has been very variously regarded, but the most generally prevalent notion was that it was a cathartic or cleansing process, a periodic ridding of the female system of some obscure impurities. As a result of this view the menstrual discharge was regarded as having peculiarly noxious properties, and the menstruating woman as being impure. This idea appears throughout all early literatures, and is familiar to us in the Mosiac law as well as in the early religious laws of Gentile nations. It has persisted in one form or another through all the ages, and customs based upon it are still legally extant amongst orthodox Jews as well as amongst many primitive peoples. It is not ten years since a cook in my own household refused on a certain day to make jam, and it eventually appeared that her reason was that she was menstruating, and that she believed that if she made jam in such circumstances it would become mouldy.

From this belief, which with innumerable variations in picturesque and frequently lurid detail prevailed universally for untold centuries, arose the equally universal custom of regarding the menstruating woman as a person to be segregated and forbidden to take part in the ordinary social and religious life of the people. From this extreme view in turn there evolved, as civilization increased, the belief, still so prevalent, that the function of menstruation produces temporarily a condition of peculiar bodily delicacy, which ought to debar the woman from, and certainly tends to unfit her for any very active exercise or concentrated mental work.

Again, while such ideas and customs prevailed in regard to the ordinary menstruation of the adult woman, the dangers from every point of view were held to be greatly enhanced at the commencement of the menstrual function in the adolescent girl. As a natural consequence of this an atmosphere of peculiar reticence and mystery has long surrounded the adolescent female in this respect, and a popular view of her special physical delicacy at this time has descended to us. Such popular views, even when based on ignorance and superstition, generally have some truth in them, derived from the accumulated experience of ages, and this last view certainly points in much the same direction as our modern physiological observations.

One other point of some practical importance seems to me to have a distinct connexion with those old traditional views of the nature of menstruation, and that is the almost universal employment of euphemisms and numerous more or less fanciful periphrases in speaking of menstruation. I am inclined to think that if we could trace this custom far enough back we should find that it originated in a superstitious fear of mentioning the menstrual function by name, lest some evil should befall the owner of such an unguarded tongue. Furthermore, I would ask you to recall to mind how many of our modern periphrases have a distinct pathological suggestion about them. We ask a woman when she was "unwell" last, or when her last "monthly illness" occurred, or when she was last "poorly," and so forth. In itself this terminological point may be a small one, but I submit that it is only one of many more or less intangible and indefinable influences which in the last generation or two have tended more by the force of suggestion than by any specific teaching to foster amongst women the idea of undue bodily delicacy at the menstrual epochs. This impression is liable to be passed on from mother to daughter—again perhaps more by the forces of suggestion and example than by precept.

The mothers of the present younger generation are, it seems to me, only slowly emerging from the influence of the traditions which used to regard a day or two in bed or on the sofa, with the comfort of a hot-water bag and the stimulus of a bottle of smelling salts, as the normal and wise mode of life for a young woman at her menstrual periods. We have, as a profession, to dispel the lingering relics of such morbid tradition, and if we can do so now the next generation of girls will suffer less from dysmenorrhoea, for we are all familiar with the vitally important part which the psychology and the mental outlook of the patient play in regard to that particular symptom. This is one of the points which the war brought home to me. I have had many patients who have told me that before the

war they suffered regularly and severely from dysmenorrhoea, but that when they were employed in the hard work of nursing or driving ambulances in France—work which brooked no interruption on account of anything but absolute physical disability—their dysmenorrhoea entirely disappeared. In some cases it began again after the return to normal existence with its opportunities for greater self-indulgence.

The other side of the picture shows the baleful influence of overwork, either physical or mental, to which I have already referred, and our business in each individual case is to try to strike the happy medium, and to inculcate in our adolescent girls a sane, healthy understanding of the function of menstruation as a natural physiological function, during which a moderate amount of wholesome exercise, which will promote the circulation through the pelvic organs and prevent constipation, is actively beneficial.

This brings me to my last point—namely, the necessity of explaining the significance of the menstrual function to girls as they reach puberty. I believe that this is best done individually rather than by class instruction, and the girl's own mother is, or ought to be, the best teacher. If the mother be devoid of the necessary wisdom, knowledge, or tact, then it may well devolve upon the school teacher, or even upon the family physician. But in every case some degree of simple teaching is, in my opinion, desirable. For the mother or responsible guardian to shirk or avoid what is always a difficult and delicate duty, and to leave the girl unprotected to absorb distorted and possibly evil teaching from her older companions, is to expose the child to the risk of shock and fear which may easily have a pronouncedly bad effect upon both body and mind, and may insidiously taint her whole outlook upon the great and vital mysteries of sex.

## II—INFLUENCE OF THE GENERAL HEALTH ON MENSTRUATION

BY

J. H. P. PATON, M.B., CH.B. ED.,

Secretary, James Mackenzie Institute for Clinical Research,  
St. Andrews

MENSTRUATION usually commences about the age of 13 or 14 in healthy girls, and is commonly believed to become established as a painless and regular function after some months. The subject for discussion includes all measures (whether in childhood, at the commencement of puberty, or during the years succeeding its onset) which favourably influence the process, either by promoting general health or by directly affecting the menstrual function.

(a) A high level of general health, attained before puberty and maintained after it, is undoubtedly the chief agent in securing normal menstruation.

(b) Measures taken during the menstrual period itself—which is but one phase in a continuous cycle of changes—are of less consequence. The regime practised during the pre-menstrual phase is probably of greater importance than that carried out during the stage of haemorrhage.

The standards by which the effect of any plan of regulation can be judged during school years are the presence or absence of pain or other morbidities and the regularity and quantity of the flow, though the final test of the efficiency of the function is child-bearing capacity when adult life is attained. The health of girls has been greatly improved since the introduction of regular games into school curricula. A high standard of physical and mental fitness is thus assured when the changes of puberty appear. With the supervision of menstruation it becomes necessary to decide whether retro games should be continued during the period or not. It is undoubtedly true that retro games may be continued by many persons during menstruation without harm and perhaps with benefit. In view of this some authorities advocate this practice in schools and assert that it results in a lowered incidence of dysmenorrhoea.<sup>3,4</sup> My experience leads me to question the validity of this conclusion and to doubt the wisdom of encouraging the habit as a school rule. I base this view upon the

results obtained in St Andrews School for Girls. I inherited from my distinguished predecessor, Dr John Moor, the rule that games, gymnastics, Swedish drill, and dancing are stopped during the first three days of the menstrual period though walking exercise is continued except by those who are definitely incapacitated. So satisfactory are the results that I have seen no reason to make any change. The girls of this school are drawn from the well-to-do classes of society. The diet, housing, and school buildings are good and the standard of health is high. I have excluded from my figures all cases in which the note were incomplete.

#### Frequency of Dysmenorrhoea

The cases of dysmenorrhoea are divided into those who suffer regularly at the "period" and those who suffer occasionally. In each group the heading "severe" includes any girl who has to lie down at these times if only for an hour or two, even when this is necessitated by faintness only. Each girl is questioned by me at her medical examination on admission to school—that is to say, as soon after the onset of her catamenia as I have the opportunity of seeing her. I do not repeat the inquiry except in case of illness. I have, however, obtained from the housemistresses information about all girls in school in April, 1927.

In the interpretation of statistical data upon such a subject the personal equation of the examiner must be taken into account while the known variations in susceptibility to painful stimuli, the influence of suggestion and the effect of intercourse it is almost an axiom influence the results.

Table I shows the frequency of dysmenorrhoea among the 78 girls questioned for the first time.

TABLE I—Girls (78) Questioned for the First Time

No pain	78.3 per cent.
Occasional pain	
Slight	8.3
Moderate	1.5
Severe	2.3
Regular pain	
Slight	5.4
Moderate	3.6
Severe	0.26
	92 per cent.

#### Ages of Girls Questioned

12 years	2	16 years	53
13	52	17	47
14	131	18	13
15	84	Not noted	2

Excluding occasional dysmenorrhoea, the percentage free from regular pain is 90.4, a figure practically identical with that given by Mrs. Clow in 1924 (89.2 per cent) for girls who played games throughout the period. As the regime adopted in the two schools differs widely it is evident that the uniform low rate in each is due to some common cause, unconnected with habit during the period.

In corroboration of my results I add a table of 253 observations made independently by the housemistresses, which agrees closely with the figures already given if due allowance is made for the improvement that undoubtedly occurs as age advances.

TABLE II—Observations by Housemistresses (253 Girls)

No pain	88.5 per cent.
Occasional pain	
Slight	10.03 per cent.
Moderate	0.77
Severe	2.3
Regular pain	
Slight	3.8 per cent.
Moderate	4.2
Severe	0.3

#### Ages of the 253 Girls

13 years	4	17 years	74
14	28	18	21
15	59	19	2
16	70		

Concerning improvement with advancing age, the only reliable data are to be got by a comparison between the symptoms of the same individual at different ages. The following table gives the results in 149 girls questioned by me on their admission to school on the first occasion, and by the housemistresses in 1927 on the second occasion.

TABLE III

	Questioned by me	Later by Housemistresses
No pain	75.1 per cent.	75.8 per cent.
Occasional pain		
Slight	10.0 per cent.	10.7 per cent.
Moderate	0.6	2.6
Severe	2.0	0.6
Regular pain		
Slight	6.0 per cent.	3.3 per cent.
Moderate	5.3	4.0
Severe	0.6	2.6

The intervals between the first and second examinations are shown below.

Years in school	No. of Girls	Years since Admission	No. of Girls
Under 1 year	33	4 to 5 years	5
1 to 2 years	41	5 years	1
2 to 3	23	Not noted	1
3 to 4	20		

The conclusion which I would suggest from these figures, when taken in association with those published by Mrs. Clow, is that the low incidence of dysmenorrhoea is attributable to a good standard of general health incident to the playing of active games, but that the continuance of games during the menstrual period is not necessary in order to obtain a low incidence of dysmenorrhoea. Is it then advisable?

In healthy individuals there is no need for any restriction of activity at the menstrual period, but the problem in school differs from that in private practice. The element of competition, to which the Medical Women's Federation has drawn attention, enters largely into the spirit of school games with the result that there is a tendency for girls to attempt to play in matches and to persist in playing hard even when suffering from some disability. Another factor in the life of the modern boarding school affects this question. The daily routine represents a continuous strenuous effort from the beginning of each term to its end. The housemistresses are all agreed that the three days' reprieve from games, etc., during the menstrual period is of great value in providing relaxation and recovery of energy. Under our present system the absence of girls from games excites no comment, and, though in many instances the prohibition is at first resented, the "three days' periodic rest" is of undoubted advantage.

#### Regularity of Menstruation

It is generally assumed that though the first few periods may occur at irregular intervals, a regular rhythm is established within a few months. Thus the following statement is made: "In healthy well-developed women between the ages of 14 and 44 menstruation occurs once a month." This is certainly not so in the school from which my figures are drawn in which for example among 78 girls questioned at the age of 17 only 43 experienced regular menstruation. Table IV shows the percentage of regularity at different ages.

TABLE IV—Percentage of Regularity of Menstruation

Age	Percentage
14-5	20.5 per cent.
13 and 14	5.8
15 and 16	62.1
17 and 19	

Intermittent amenorrhoea is the type of irregularity present. If the common belief is true it is impossible to view the figures without alarm since they indicate a persistent deficiency of ovarian secretion in a large proportion of the potential mothers of the future. Upon inquiry it is commonly found that a normal period occurs during the holidays in girls who are amenorrhoeic during the school term. In my opinion the cause of this defect is to be looked for in the long hours of continuous effort, mental and physical, imposed upon the adolescent girl by the modern school curriculum. Munro Kerr makes the following statement:

It is an interesting fact that the very athletic and the who a occupation involves great physical and mental strain have in many instances a relatively poor menstrual discharge.

Professor McIlroy writes

When girls at puberty are urged to work for examinations the first danger signal is often amenorrhoea or irregular scanty menstruation, and she urges that great care must be taken to find out if the individual is of a normal standard of health before permitting strenuous games or strain of study.

Rosenau<sup>7</sup> makes some statements which are of interest in this connection

"The effect of overwork upon fecundity and upon infant mortality is impressive. Biaggi states that of 172,365 Italian women between the ages of 15 and 54 years who were employed in industrial occupations the average child bearing coefficient was only about one third of the general fertility of Italian women."

I direct your attention to this matter as of prime importance in connection with menstrual health and one upon which this Association might collect information and provide authoritative guidance to school authorities. Many of these exact from girls under their care an amount of daily effort, mental and physical, which few adults could undertake. The result of this, coupled with the anxiety associated with competitive examinations and games, is, I believe, reflected in the figures which I have just quoted.

I have been unable to find in the available literature data upon which this question can be decided. Comparative tables in regard to the frequency of regularity among girls leading sheltered, moderately strenuous, and fully strenuous lives would be most informative.

### III—THE PREVENTION OF MENSTRUAL TROUBLES.

BY

ALICE E. SANDERSON CLOW, M.D., B.S., B.Sc.,  
Cheltenham

My observations on the matter under discussion have been made during a period of fifteen years of general practice, including fourteen years' experience of medical inspection at a large school for girls and of seven years' medical attendance at a training college for teachers. The school-girls, except in a few instances, are not my own patients, but are referred for treatment to the medical men attending the boarding houses. I have excluded from consideration all cases in which there is disease of the pelvic organs, my remarks refer only to girls in good health.

#### Age of Onset of the Catamenia

One of the most striking things in studying the normal menstrual function is the variation in the age of onset of the catamenia in girls of normal development. In my experience it has varied from 8 to 19 years.

The accompanying list gives the percentage of the various ages of onset obtained from the girls at the school and the training college.

Age of onset.	School (1137 girls)	Training College (300 girls)
8	0.08 per cent	0.00 per cent
9	0.08 "	0.00 "
10	1.05 "	0.33 "
11	4.92 "	0.33 "
12	16.79 "	8.33 "
13	34.12 "	21.66 "
14	26.82 "	37.33 "
15	11.08 "	22.00 "
16	4.41 "	8.00 "
17	0.35 "	2.00 "
18	0.17 "	0.00 "
Before 14	57.04 per cent	30.65 per cent

The figures show that the age of onset was, on the whole, earlier in the schoolgirls, where 13 was the most usual age, than in the college students, in most of whom it was 14. It will be noted that over half of the former (57 per cent) began to menstruate before they were 14, whereas less than a third of the latter (30 per cent) began before that age.

The schoolgirls are the children of educated parents in easy financial circumstances. The college students come from humbler, though not necessitous, homes from various parts of the country, and in most cases began their education in elementary schools. Although the standard of health among the latter is good, the schoolgirls are, on the whole, of better physique. It would seem, therefore, that earlier development of the generative organs is asso-

ciated with physical fitness. It must be noted that, whereas the number of schoolgirls from which these figures are obtained is over 1,100, my experience in the case of the students has, so far, been limited to 300.

A difficult, but very important, question to decide is, When does the delay in the onset of the catamenia become pathological, and how soon should treatment, if any, be begun? Most parents become anxious if the menses have not appeared before the fifteenth birthday. In searching for an answer to this question, I have tabulated the annual increase in height and weight of these girls who have been at the school for several years before and after the onset of the catamenia. In order to show the relation between the rate of growth and the age of onset I have divided the figures into three groups, according to the age at which the menses appeared, as follows:

	Ages	
Group I	11 and 12	50 girls
Group II	13 and 14	188 "
Group III	15, 16, and 17	60 "

— = INCREASE IN HEIGHT (UNIT = 1/2 INCH)  
----- = INCREASE IN WEIGHT (UNIT = 2 LBS)

The graphs represent the average rate of increase in height and weight in the three respective groups; therefore, until they touch the base line growth is continuing. The thick vertical line indicates the year during which the onset of the catamenia occurred. The vertical spaces represent the four years preceding and the four years subsequent to the year of onset.

The following facts are brought out by the charts in all these groups:

- 1 The maximum growth occurred during the second and third years preceding the onset of the catamenia, followed a year later, by the maximum increase in weight.
- 2 During the year in which the menses appeared there was a definite fall in the rate of growth in both height and weight.
- 3 Growth in both respects continued for at least two years after the onset of the catamenia.
- 4 Notwithstanding the difference in age in Groups I and III there is a marked similarity in the curves.

In studying the actual figures one was struck by the facts:

- 1 That there was no exception to the rule that growth in height and weight took place, but at a reduced rate, after menstruation had begun.
- 2 That, although the majority of girls had ceased to grow at 16, and many had by that time begun to lose weight (the normal occurrence in girls soon after growth is completed), nevertheless, those in whom the onset of menstruation was delayed until 16 or 17 years continued to grow until they were 18 or 19, whereas those who began to menstruate early ceased growth correspondingly early.

These facts incline me to the view that we are not justified in regarding a case as one of primary amenorrhoea, or in attempting to interfere with the natural course of events, so long as growth in height and weight continues.

The cases which give cause for anxiety are those in which the secondary sexual characteristics have not begun to develop by the age of 15, especially if the rate of growth in height and weight has begun to diminish. After the age of 17 this must be a rare condition. I have only come across two cases in the 2,600 girls I have examined, and two adult cases in my own practice. Both of the girls, now adult, have remained sexually undeveloped in spite of treatment from the age of 14. Endocrine therapy had no apparent effect.

#### Interruption of the Regular Periodicity

Of the three types of secondary amenorrhoea which I have noted as peculiar to adolescence, one only is of serious import, and belongs to the realm of medicine rather

tion of hygiene. I have found irregularity of periodicity in the majority of girls (54.5 per cent.) during the first two years of menstrual life. The cases of amenorrhoea are more numerous among the boarders than the day girls; they are usually associated with any disturbance in health and in my opinion, seldom call for medical treatment.

#### Sanction Associated with the Menstrual Period in Young Girls

I can state with certainty that menstruation can be, and therefore should be, free from suffering of any kind. This was the case in 89.2 per cent of the schoolgirls at their last review and in 94 per cent of students on leaving the training college. We can consequently take it as a fact that when menstruation is normal the girl is free from any pain, headache, sickness or feeling of discomfort. This is the state of affairs we have to aim at for every girl in the country. It would help to bring this about if inquiry into the menstrual function were recognized as an integral part of the medical inspection of girl in school and university. It seems that the existence of the menstrual function has been ignored by school doctor in the past. The keeping of records would not only provide us with valuable information, but would give patient requiring aid the opportunity of receiving attention early enough to prevent the onset of serious trouble.

It is very rare for any symptoms to occur during the first few months of a girl's menstrual life, as far as I can ascertain it occurs in only about 2 in 1000 cases. This fact is worthy of thought, especially when it is coupled with the fact that when I first began my work at the school I found that 220 in 1000 cases had developed some menstrual trouble within four years of the onset of the period. If a girl is allowed to be guided by nature as to her behaviour during the period she will, in nearly every case, carry on as usual. The desire for activity whether it be in games or work is no more diminished than is her desire for food or sleep.

Most educated mothers teach their daughters that they must not expect to feel well at these times and that they must modify their habits of life accordingly. They are told that it is dangerous to have a bath or even to wash, especially the feet. They must give up their games and drilling at school and all avoidable exercise and, if possible, spend part of the day lying down. Every year I come across scores of girls who have received this teaching and in nearly every case there is a spontaneous expression of pleasure when I tell them that provided they obtain consent from home they may have their warm baths and even join in such games as hockey and tennis and do drilling and gymnastics as usual. I lay special stress on the importance of taking this exercise on the first and second days of the period.

The result of this instruction which has been given for the last thirteen years to each individual girl who has arrived at the age of puberty, is that the proportion of those who suffer at the period has been reduced from 40.7 per cent to 10.8 per cent. The 10.8 per cent of sufferers consist mostly of those who do not succeed in getting permission from home to take the necessary exercise. Given free scope we could I believe abolish practically all menstrual suffering in healthy girls under 18 years and if the habits with regard to exercise acquired by that age were continued into adult life suffering at the period would I believe, be a rare complaint. I have already published figures and cases in support of these statements, and have referred before to the leaflet *Advice to Girls Concerning the Monthly Period* issued by the Medical Officer of Schools Association in which the continuance of baths and vigorous exercise throughout the period is recommended. Many thousands of these and of similar leaflets published by the Medical Women's Federation have been distributed to schools and factories and I look forward to the time when all healthy girls will be brought up in accordance with the hygienic measures therein advocated.

Girls engaged in sedentary or standing occupations are the greatest sufferers from dysmenorrhoea. This will continue until employers of women workers realize, as some already have to their own advantage, that this disability, and consequent loss of work, can be stopped by giving opportunities for daily exercise, such as could be obtained by fifteen minutes drilling preferably in the open air.

There is no doubt that the neurotic disturbances connected with menstruation are generally produced by undue suggestion and example and that the cure lies in inculcating sound views with regard to the menstrual function, resulting in healthy activity of mind and body during menstruation as at other times.

The prevention of menstrual troubles lies with the parent, the schoolmistress, the school doctor and the employer of women workers. With healthy conditions and influence in the home, the school and the factory I believe that there would be but little call for treatment of menstrual disorders in otherwise healthy girls.

Presented at the Meeting of the British Medical Association, 1917, 2nd July, at the Royal Albert Hall, London, 1917, 2nd July, 1917.

#### Discussion

Mrs. ITHUR VACHAN SAWAY (London) said that menstruation might be regarded as a vigorous pregnancy; it should be painful and should not interfere with the ordinary activities of life. Normally the only concomitants should be a certain lassitude and some increase of nervous tension. She was firmly of opinion that there was a close connexion between dysmenorrhoea and the toxæmias, particularly the exanthems of childhood, like scarlet fever and measles. In many cases of dysmenorrhoea there were associated septic tonsils. Just as the fevers caused a weakening of the musculature of the heart so did they affect the uterine muscle. The occurrence of anteversion and more rarely of retroflexion, might be traced to softening of the muscles produced by one or other of the diseases of childhood. At one time it was quite common to meet with severe cases of salpingo-oophoritis following a severe attack of enteric fever. In regard to the question of hygiene she advocated daily warm baths but was opposed to cold baths and sea bathing during the period. She thought that moderate exercise was undoubtedly beneficial, but strenuous game might be rather too much.

Dr. C. L. STANLEY (Cardiff) dealt with the mental aspect of the hygiene of menstruation as seen in the practice of a mental hospital. From a study of about 200 mental patients he had found not in whom the onset of insanity could be definitely attributed to the onset of menstruation. In cases where menstruation was influenced in mental disease it was usually in the direction of excess, and he had found no justification for the textbook statement that insanity was usually accompanied by amenorrhoea. Before puberty girls should be informed of the coming event and should be impressed that it was quite natural during uncomplicated menstruation in absolutely normal life should be led with regular exercise and bathing. Irregularities in the first few years were seldom important and might be disregarded.

Prof. G. GIBSON FITZGIBSON (Dublin) said that schoolgirls were generally brought to see a gynaecologist on account of amenorrhoea very rarely for dysmenorrhoea. He thought that the cases of severe disabling dysmenorrhoea at the age of 20 to 25 were nearly all acquired dysmenorrhoea in which no trouble had been experienced in the earlier years. The cause required further investigation. In the case of girls with dysmenorrhoea dating from the onset there was commonly some definite pelvic disease, which might quite probably be traced to the acute infections of childhood.

Prof. J. J. McILROY (London) agreed that every healthy girl should regard menstruation as a normal function, cases of dysmenorrhoea were rare before the age of 18. Girls without occupation suffered most frequently from dysmenorrhoea, having nothing to do, their attention was focused on their sexual functions, and not infrequently

It is obtained from the Secretary, Medical Women's Federation, 4 Clarendon Road, Brixton, S.W. (1s. 8d. per 100; 7d. free).

they were cured by marriage. In factory girls the incidence of dysmenorrhoea was very low and was confined, as a rule, in this class to clerks and those whose occupations necessitated sitting all day. She did not regard dilating and curetting in these cases or occupational dysmenorrhoea as of any value, the only remedy was to advise exercise, dancing being one of the best forms. She was convinced that vigorous games had nothing to do with sterility, whereas mental stress might be held responsible.

Dr. CATHERINE CHISHOLM (Manchester) stated that her figures, obtained from schoolgirls of a different type from those studied by the openers of the discussion—namely, the industrial type—were nevertheless remarkably similar. The incidence of dysmenorrhoea was much higher in active working women than among schoolgirls. She thought that the nervous strain of examinations or overwork was a potent cause from the failure of the general health arising therefrom. Similarly in sedentary workers it was the impairment of general health which resulted in dysmenorrhoea. It was very important, especially in day schools, that games should be made part of the curriculum, not added to an already overcrowded programme.

Dr. MABEL L. RAMSAY (Plymouth) said that though she had charge of a school of 200 girls the only cases of dysmenorrhoea she ever saw occurred at about the ages of 20 to 25. The economic aspect of bettering the working girl's condition was of supreme importance. Dysmenorrhoea was generally associated with some error of bodily growth. She strongly deprecated the wholesale removal of tonsils, and said that the public were becoming seriously alarmed in this matter. She agreed that the specific fevers, especially mumps, might often give rise to pelvic troubles. She did not approve of too many hot baths, but preferred to continue with cold baths and sea bathing.

Dr. FARQUHAR MURRAY (Newcastle) had seen a large number of girls, aged 18 or 19, who had never menstruated, and examination showed a definite lack of development of the uterus. Cases with very scant menstruation were often associated with dysmenorrhoea. To stimulate the development of an infantile uterus treatment must be begun early, and endocrine therapy should not be delayed until they thought that bodily growth was complete. Profuse menorrhagia in adolescents was sometimes a very difficult problem. He deprecated hysterectomy in young girls, while a rays and radium generally damaged tissues with which they came in contact.

Dr. LILIAS M. JEFFRIES (Brighton) did not agree that violent exercise should be forbidden. She advocated leaving it to the housemistress to decide which girls should be permitted to play games. She thought that there was an insufficient provision against the occurrence of constipation in schools. Hockey was no more vigorous than Swedish exercises, but she disapproved of sea bathing. She denied that fecundity was adversely affected by vigorous games and exercises.

Professor J. HENDRY (Glasgow) maintained that it was of even more importance to attend to the general health during the intervening twenty-eight days than during the actual period of the flow. He favoured vigorous exercise during the whole month, such as tennis and badminton, and not merely walking. He did not think that modern dancing was vigorous enough to serve this object. In hospital practice the difficulty was to get patients to carry out the advice given to them, and it was in this connexion that they must look for improvement by the establishment of welfare centres.

The PRESIDENT commented upon the much diminished frequency of anaemia nowadays compared with thirty years ago, but thought that this caused a later commencement of dysmenorrhoea. He referred to the great improvement in conditions in the elementary schools where girls were no longer forced through various standards regardless of all considerations of health.

Dr. W. F. T. HAULTAIN (Edinburgh) thought that constipation had a great deal to do with dysmenorrhoea in girls about the age of 18, and suggested that girls should

be encouraged to drink more water. It was particularly necessary to treat the constipation which occurred during the week prior to menstruation, since of the constipation often relieved dysmenorrhoea. Cold baths should not be allowed as they tended to stop the flow, whereas hot baths and exercises increased it. He thought the association between dysmenorrhoea and the specific fevers was too vague to be relied upon.

Dr. B. M. SUTHERLAND (Australia) thought that the big factor in diminishing the occurrence of dysmenorrhoea was the great increase in open-air exercises for girls in these days. He urged the necessity of treating every case individually and not by applying a general routine to all regardless of individual peculiarities. He warned them that the statistics of chosen schools could not be applied indiscriminately to the general public. He spoke favourably of shower baths instead of plunge baths and strongly opposed sea bathing during the flow.

Professor JOHNSTONE, in replying, said that there was an enormous amount of evil done by suggestion, whether unconscious or otherwise. He agreed that in regard to hygiene the pre-menstrual days were if anything of more importance than the actual period. The question of constipation was of great moment, miracles could be performed with the aid of magnesium sulphate. General principles being agreed upon, every case must be treated on its merits.

Dr. PAVOV defended the rule against violent exercise by pointing out that though some girls might suffer as the results of it, others would be saved from the suggestion of invalidism from which they could not escape if they were singled out as individuals. He had always thought that constipation had a very important bearing on dysmenorrhoea, but on investigation he was surprised to find among his limited numbers that there was no apparent connexion. They were not in the habit of taking any special precautions at the first menstruation, and no harm had resulted so far as he knew. He was disappointed at not hearing more about persisting irregularities.

Dr. ALICE CROW had found no dysmenorrhoea or amenorrhoea among girls working for examinations. It was very rare for a girl to leave after a strenuous course at the training college with any menstrual trouble at all. She thought it lamentable that even 10 per cent of dysmenorrhoea occurred, and she believed this could be wiped out by exercise, suggestion, and so forth. Dilating and curetting were quite unjustifiable.

## THE POLICE SURGEON IN RELATION TO FORENSIC MEDICINE.

### THE TEACHING OF FORENSIC MEDICINE

BY

JOHN GLAISTER, M.D. GLASG., D.P.H. CANTAB.,  
F.R.C.P.S. GLASG.,

Professor of Forensic Medicine, University of Glasgow

THE duration of the course and the range of teaching of the subject of forensic medicine to students of medicine have long occupied the attention of teachers as well as of the General Medical Council.

For many years the subject has been a compulsory part of the examination for degrees and diplomas, and consequently of the medical curriculum of study. Owing to its character it is one of the final year classes, inasmuch as it is expected to deal with the previous subjects of the curriculum which may have a bearing on the law of the country, in accordance with the definition of forensic medicine, which is—that subject which correlates medical knowledge to the purposes of the law.

If one makes a general survey of the medical curriculum

\* A paper read in opening a discussion in the Section of Forensic Medicine at the Annual Meeting of the British Medical Association, Edinburgh, 1927.

it will be apparent that many if not indeed most of the subjects which are treated in forensic medicine are practical and of the nature of the things which are done in the hospital.

The student of anatomy has to spend much time in the anatomical laboratory and also the student of physiology the student of surgery and of medicine spends some years in the wards of the hospitals acquiring practical acquaintance with the various phases and kinds of disease and their method of cure in addition to some laboratory work in operative surgery and in the practical aspects of medicine in midwifery he has to be certified as a witness at and so many cases of childbirth and to show some knowledge of general pathology in chemistry the amount of knowledge which he can absorb in the time allotted for his study although inclusive of some laboratory work at the best periods of but a very circumscribed sphere of knowledge, in no way his requirement must be reckoned as elementary although he has opportunities of distinguishing between plants and fruits which are poisonous from those which are non-toxic in pathology he may gain some knowledge regarding these lost topics of life which play such important parts in the production of the diseases of animals and of man, in materia medica he is made more familiar with poisons and drugs for curative purposes and in pathology he is brought face to face with the pathological aspects of diseased organs as contrasted with those in health and he is supposed to pay sufficient visits to the post-mortem room as will enable him when called upon to conduct effectively a post-mortem examination for medico-legal purposes. But all of these in addition form the subjects of didactic lectures which the student is bound to attend. Comprehended within such knowledge which he so requires as or ought to be his facility of applying that knowledge to practical medico-legal work.

It may be said that while in the hospital wards, he may be able on occasion to see odd cases of poisoning—such opportunities are relatively rare and that in the outpatient department he can see the results of injuries from many and different causes. All this undoubtedly ought to be helpful to the student, but he has to keep in mind that sooner or later, when he becomes a duly qualified registered medical practitioner he is likely to be called upon to deal with very many problems, occasionally some of them especially difficult, which will compel his attendance as a witness in courts of law. Hence the more purely legal aspects of forensic medicine come into prominence and the class of forensic medicine is the only opportunity of becoming acquainted with these, in addition to his reading.

From the nature of the subject itself forensic medicine is, therefore, apt to be one of the few subjects which are not capable of being readily applied with practical tuition in all their phases.

From his profession the practitioner is expected to render assistance to cure and if possible to save the lives of his patients, but he can never rid himself of the likelihood that the doing of this may involve his appearance in the witness-box as a skilled witness whose object ought to be to assist the court in arriving at an intelligent knowledge of the medical aspects of the case for the elucidation of some of which careful observation and logical thinking are always much needed. Two things are essential in medico-legal work, first, careful observation and record of the facts of a case and, secondly, logical inferences or deductions from these facts. It has been truly observed that the differences in medical testimony not infrequently witnessed and heard in law courts emerge more frequently not so much from the facts of a case as from the inferences or deductions made therefrom. The value of a witness to be of assistance to a court will therefore much depend upon his scrupulous consideration of both of the elements.

It has sometimes been urged that instruction in forensic medicine as in some other subjects may as well be obtained from books as from lectures. While there may perhaps be something to be said for this view, the value of lectures will largely depend, if not almost entirely upon the practitioner's experience of the lecturer. This goes without saying, but there is a great difference of value between the lectures given by a teacher who is in constant and immediate touch with the practical aspects of forensic medicine

and those given by one whose knowledge is chiefly theoretical and obtained from books. Over an experience of for five years as a teacher of this subject to students of medicine and of law the foregoing observation has impressed itself more and more on my mind.

That leads to the question whether forensic medicine courses could be better arranged than at present so as to afford the student a more active and practical acquaintance with the subject.

I think it can be said with truth and appositeness that in Scotland the universities and colleges have taken the teaching of this subject as an important item in the curriculum of the general practitioner. Chairs have long been founded in three of the universities and a lecture ship in the fourth the length of the course being determined by the university ordinances and the regulations of the General Medical Council. Examination papers are set for that subject at each final degree examination and thereafter each student is examined orally and practically. In the Scottish colleges the subject for diploma purposes is largely treated with public health two questions in each subject are set for answer and an oral examination follows.

Is there any feasible and workable plan by which the average student might acquire more practical knowledge than hitherto he has been able to gain or is obtaining at present?

It has been suggested that during the curriculum the attention of the student might be directed to the medico-legal aspect of each subject in medicine for example to the differences in behaviour of acute and chronic exanthemata and diseases and the acute and chronic forms of irritant poisons; in surgery to the significance of wounds and wounding from the point of view of conviction in relation to how common plants and fruits are poisonous and which non-poisonous in pathology not merely to see that the student has attended so many post-mortem examinations but that he has actually assisted in making or has himself performed at least one complete dissection. While that is not impossible the retort comes that no teacher has sufficient time to teach even the subject with which he is charged without traversing other fields. But even on the supposition that this were possible it must be obvious that there are many departments of forensic medicine comprehended in criminal charges which the student cannot observe in his ordinary curriculum. For example he is hardly likely to see a case of infanticide or criminal abortion or to have seen carried out in detail the lines of investigation regarding promotion of crime in the form of suspicious stains for blood on garments or weapons, or for semen in charges of rape or of stains in cases of throwing of vitriol or other corrosives. Taking however more ordinary things first such as making a proper post-mortem examination for medico-legal purposes it seems to me that the average young practitioner at present has had little if any experience. But he may be called upon in England on the summons of a coroner to make or assist in making such an examination. In Scotland on the other hand the duty of appointing the medical practitioners to perform this work is in the hands of the procurator fiscal of the county in which the examination has to be made, and only once then when a warrant of the sheriff has been issued in set terms incorporating the names of the practitioners who are to conduct the examination. This duty in Scotland is made to devolve on experienced practitioners only because very important issues may emerge from their examination respecting the cause of death, if such as is commonly the case be a culpable cause.

There are in Scotland two classes of medical practitioners who are more or less constantly faced with medico-legal questions. These are (1) police casualty surgeons, and (2) medico-legal examiners appointed by the Crown for that purpose.

The police casualty surgeon obtains his appointment from the magistrate and town council as in Glasgow Edinburgh, Dundee and other places. The range of his duties embraces the examination of persons alleged to be "drunk" or intoxicated from alcohol the examination on first-aid treatment of persons alleged to have been injured or assaulted the examination of the bodies by inspection only of those who have died suddenly or under suspicious

circumstances, examination of children alleged to be the subjects of neglect and ill-treatment by parents or guardians, the examination of the mental condition of alleged insane persons found wandering in the streets or behaving there in an insane manner, and the examination of children and young persons alleged to have been criminally assaulted. These, perhaps, comprise the main duties of his office. In some instances, however, his duties may involve medical attendance on members of the police force, although in some places, as in Glasgow, these are not included.

The medico-legal examiner has a different range of work to pursue if and when called upon. He will be expected to perform all *post-mortem* examinations of the bodies of persons with respect to whose deaths there is alleged to be suspicion of or actual culpability, and to make reports of the results to the procurator fiscal, from whom their warrant comes from the sheriff, and to make examinations of productions regarding the nature of certain suspicions stains thereon, connected with a criminal charge against a person apprehended or still at large, by laboratory methods. All these investigations—and they are of varied character—demand the most exacting care and attention to secure accuracy of results, since from these and the inferences therefrom the release of a prisoner or an indictment for a crime of a serious kind may depend. It is obvious that such examinations as the foregoing cannot be entrusted to the hands of a novice or inexperienced person. In charges of murder, for example, it is likely to be that the same medico-legal examiners who make the *post-mortem* dissection will also have the duty of examining such productions as the Crown may deem necessary. In the examination for blood-stains, for example, much time and painstaking work must be devoted in order to ensure accurate results, and especially, as more frequently happens nowadays, the examiner is expected to be able to prove whether the blood, if found, is that of a human being or not. When the investigation involves toxicological search, the medico-legal examiner will likely be associated with an expert chemist, and thus the Crown will receive a joint report. In the foregoing, therefore, are fields worthy of cultivation, which might be utilized for the purposes of practical teaching in forensic medicine.

In the light of what has preceded we now approach an answer to the question. What scheme, if any, might be evolved for the better practical teaching of the student in forensic medicine?

Experience indicates that the first essential of likely success in teaching this subject will be that the teacher should himself be actively engaged in a branch of the profession which deals largely with medico-legal problems, either in the capacity of a police casualty surgeon or as a medico-legal examiner. Such positions afford material ready to the hand of the teacher whereby he may illustrate many points of his teaching, while the medico-legal examiner as teacher, by utilizing the services of a few students at a time as assistants in examination of cadavers, will afford them opportunities of observing how to act and how to frame reports. Such a class of teacher has, moreover, an excellent chance to collect photographs of cases which, shown as lantern slides in the lecture room, will pictorially illustrate to an entire class several points of interest. Laboratory investigations may also be given to classes of students either in the lecture room or in the laboratory itself, and demonstrations of microscopic objects and museum jar specimens can similarly be exhibited. All of the foregoing methods I have combined for many years past. The formation of a class museum of illustrative specimens is a valuable adjunct.

The more definitely legal aspects of the subject must in the main be treated didactically by lectures. The law has to be expounded in an easy manner to induce attention, for it is my experience that the average student fights shy of law, not realizing that such a knowledge is likely to conduce later to his comfort and assurance in doing medico-legal work. There must be a simple exposition of the laws of evidence, of the functions of the General Medical Council and its powers of discipline on those registered as medical practitioners, the penal offences constituting "infamous conduct in a professional respect", some things must be

said respecting the law of infanticide, etc., as to nullity of marriage, as to sexual crimes, and to insanity with respect to responsibility for crime, and several others. The subjects having medico-legal importance to the profession have, however, increased in later years—such, for example, as the National Health Insurance Acts, Workmen's Compensation Acts, Notification Acts, the Cremation Act, Death Certification, etc. The student will benefit by some instruction on these subjects, for to many young practitioners the quickest avenue to general professional work is the acquirement of a panel of patients, and sooner or later he may receive an appointment as a certifying surgeon, and become eventually, perhaps, a medical referee under the Compensation Acts. Judges have on occasion expressed the view that there are no witnesses so difficult to be heard or so difficult to be understood as medical witnesses—difficult to be heard from want of audible speech in giving evidence, and difficult to comprehend because of the nature of their evidence. The medical witness in a court of law must remember that medical language is not understood by an ordinary jury, however much better it may be by counsel and judge, hence he must avoid the use of technical medical language.

A visit of a student to a court of law during a trial is worth much, in so far as it enables him to see the surroundings, hear witnesses being examined-in-chief and cross-examined, and to observe the conduct in these of members of the Bar. I have found it an excellent plan to recommend students to attend the sittings of sheriff and jury courts, and of the High Court of Justice when available, while trying criminal cases. Such opportunities commonly occur during the progress of a teaching term, and courts, as I have found, are most willing to give students facilities for being present.

Some such scheme, broadly sketched and as has been carried out, may be reckoned to make the course of teaching forensic medicine not only more interesting during the student's career, but also further calculated to turn him out after graduation or qualification a better equipped man for the medico-legal side of his work.

#### DISCUSSION

Professor J. E. W. McFALL (Liverpool) considered that the teacher should be one who had gained experience by being in touch with the problems involved, for that he should hold in appointment as police surgeon. He should also be an efficient pathologist in order to gain the confidence of the coroner. In England the subject was taken too early in the student's course, and should be left to the final year. The actual forensic investigations should be organized into a service since it present so much depended on the inclination or prejudices of individual coroners.

Professor SYDNEY SMITH (Cardo) considered it necessary to provide means for the education, not only of the student, but also of the medical practitioner, in the subject of forensic medicine. The course of lectures and practical training of the student was comparatively easy to arrange, and was not of the same order of importance as the instruction of the practitioner. In this country there appeared to be no definite status for the medico-legal expert and any medical practitioner might (and did) perform *post-mortem* and other examinations in medico-legal cases and give evidence thereon. When it was considered that the medical evidence in a criminal case might result in the loss of life or liberty of an individual, it seemed most improper to allow evidence to be given except by a person with special training in the particular subject. There must be quite a considerable amount of crime undetected or unsuspected on account of the want of special knowledge of the examiners. The training of specialists in the subject of forensic medicine must include practical experience in a medico-legal department, and such a department could exist only by obtaining all the medico-legal cases for definite districts. It would also give the legal authorities a definite place to which they could send all their material for opinion, and where the investigating authority could obtain advice and assistance in cases where technical knowledge was required. The beginning of some

such a form was advocated some time ago when the Medical-Legal Society in London decided to urge the formation of a medico-legal institute. It should be possible to establish such institutes not only in London but in other centres so arranged that the whole of the medico-legal work of the country could be under expert supervision. The speaker instructed the conditions in Egypt, where all medico-legal cases of any importance came automatically under the notice of the Medico-Legal Department of the Ministry of Justice. This department, which consisted of whole-time medical officers, chemists, and other officials was attached to the Parquet as investigating authority. All cases of poisoning in whatever part of the country they occurred, all examinations of blood and other fluids and in fact all technical examinations, were carried out in the central laboratories at Cairo, while experts were available for advice and assistance in the different centres. A similar scheme could readily be inaugurated in this country and the cost would almost certainly be less than the cost of the present haphazard system of payment to different local practitioners. The speaker gave actual figures for his own department which showed that if the work done had been paid for by the case the cost to the country would have been about four times as much.

Dr A. ALLISON (Glasgow) regretted that students and most practitioners had to rely on accounts of cases. The average man was only rarely called to court, and if he had a special interest in medical jurisprudence it was difficult for him to obtain the necessary post-graduate instruction. If the teaching of forensic medicine was to be improved three things were required: (1) increased opportunities for personal observation on the part of both undergraduate and post-graduate students; (2) opportunities of gaining experience in laboratory investigations; (3) opportunities for the discussion of medico-legal problems, preferably in a mixed society of doctors, lawyers, and other interested persons. Much might be done by organization to satisfy these three conditions. In towns having a medical school a centre for *post-mortem* examinations might be provided by the local authority, but it would probably be better if an arrangement could be made with the pathological department of a hospital. It would be an advantage if all cases of poisoning admitted to hospital were collected into one ward. In any big hospital there would be enough cases annually to demonstrate the effects of the commoner accidental and suicidal poisons, and laboratory work could be easily arranged. For the post-graduate student intending to follow the special work of forensic medicine full facilities ought to be provided. The only medico-legal society in Great Britain held its meetings in London, yet in all large centres there were many doctors and lawyers interested in medico-legal problems and provincial societies should be formed. Academic study should be supplemented by practical experience, which could be obtained by assisting a police surgeon in his routine work.

Dr DOUGLAS KEPP (Edinburgh) pointed out that a medico-legal service could grow up in a similar manner to the public health service, the first essential being that one man specially interested, and later one specially qualified, should be officially appointed for a given area. All forensic questions and *post-mortem* examinations in the area should be referred to him in the first instance, and not be undertaken by practitioners ignorant of this branch of medicine.

Professor J. T. J. MORRISON (Birmingham) said that medico-legal practice in England in the sphere of crime was not encouraged in due proportion to its legal and social importance. The financial departments of public bodies were reluctant to authorize coroners to return the services of medical experts in elucidating complex problems where crime or unnatural death was known or suspected. Too often it was thought that *post-mortem* examination might be assigned to any doctor, and investigations demanding special skill and knowledge were entrusted to persons who were unfamiliar with the questions to be solved and with the procedure involved in their solution. He deplored

the fact that forensic medicine was put in the background in English teaching centres, and was frequently taught by men who were not in touch with medico-legal practice.

Dr HINCKS (Hull) instanced cases of difficulty to the general practitioner.

Lord RESSALL said that since the medical curriculum was already so heavy he was glad to hear suggestions of post-graduate teaching in this subject.

Sir W. SCHEMPP (Coroner for Central London) thought there should be a central mortuary where *post-mortem* examinations could be made and under certain regulations, be open to persons who wished to obtain knowledge in pathology and to be taught forensic medicine. The teacher should be one whose duty it was to deal with dead bodies and that was in a majority of cases, the police surgeon. The difficulty was that the work of the police divisional surgeon was not sufficient in itself to employ his whole time; private practice would not tend to increase his interest in criminal work.

Prof. G. LAYSTON, in reply, said that after many years of work as police surgeon and medico-legal examiner in Glasgow he agreed that the police should know something of the elements of medical jurisprudence, and for some years now the police and detective departments had received instruction on that subject. Thorough *post-mortem* examination was an important part of a medico-legal examiner's work, and in Glasgow there was a centre where bodies were brought for this examination. Financial considerations prevented many improvements being added.

## THE ABUSE OF CAESAREAN SECTION

BY

HENRY HILLITT M.D.,

FORMERLY SAVERY POTTERY HOSPITAL MEDICAL CONSULTING  
OBSTETRICIAN TO THE HEALTH DEPARTMENT OF NEW ZEALAND

ONE great difficulty I have in writing on the abuse of Caesarean section is that almost everything I can say on the subject has been anticipated by Prof. or Whitridge Williams of Baltimore and has been put much better than I can put it. In what I say, however, I am not merely repeating. In view—my own have been formed independently, but they coincide with his. Even in 1917 he anticipated the title of this paper. On the other hand it is a very great advantage to have his authority to support my own attitude. In 1916 when addressing the Clinical Congress of Surgeons of North America he spoke as follows:

Unfortunately history shows that advances in the practice of medicine and surgery are rarely attained in a thoroughly rational manner but that a period of undue enthusiasm or even of almost reckless abuse usually precedes the establishment of the actual value of a given procedure. I believe that we are at present going through such a stage in connexion with Caesarean section.

Again, in the last edition of his *Obstetrics* he writes as follows:

With the increasing perfection of surgical technique and an erroneous idea of the safety of the operation there seems to be a growing tendency to regard Caesarean section as the simplest means of coping with most obstetrical difficulties. At the present time I consider that the operation is being abused and that not a few patients are sacrificed to the *furor operativus* of obstetricians and general surgeons who are ignorant of the fundamental principles of the obstetric art. The being the case the conscientious obstetrician should be particularly careful in the recognition of indications or Caesarean section.

It would be an easy matter to quote similar opinions presented by other writers, but I think Williams's authority is sufficient. I think, too, that if together with the statistics which I shall put before you, will establish my two main points.

First, that Caesarean section should be avoided whenever possible on account both of its immediate risk and of its possibly crippling effect on the patient.

This paper read before the Australasian Medical Congress at Dunedin, New Zealand, early in 1917, has been a little curtailed and some appendices and statistical tables omitted in order to ensure publication.

Secondly, that Caesarean section is seldom necessary, because the art of midwifery provides a more satisfactory alternative.

The mortality following Caesarean section varies directly according to the stage at which the operation is done. The figures collected by Holland in 1821 prove this very clearly. Caesarean section for contracted pelvis done before labour begins caused a mortality of 14 per cent, early in labour a mortality of 18 per cent, late in labour a mortality of 10 per cent, after a preliminary induction of labour a mortality of 14 per cent, after attempted forceps a mortality of 25.7 per cent, after attempted craniotomy a mortality of 50 per cent. I wish to emphasize the fact that even when the operation was done under the most favourable circumstances the mortality was 14 per cent.

This is a low mortality—lower, perhaps, than is actually the case. Williams's corrected statistics for all cases in his hospital—corrected by the exclusion of deaths which were not attributable to the operation—give a mortality of 3.35 per cent. He divides his cases into two periods. In the first period he operated at any time during labour, often after a prolonged second stage. The mortality was 12 per cent. In the second period the operation, whenever possible, was done before, or a few hours after, the onset of labour. The mortality was 2.45 per cent. Further, he considers that the general mortality in the United States of all cases is 10 per cent.

The cost of Caesarean section done late in labour is very high. As Williams says, the evidence is clear that whenever a considerable time has elapsed between the onset of labour and the performance of Caesarean section, we must take into consideration the probable existence of a latent infection, which may later give rise to a general peritonitis. To prevent this there is apparently only one remedy, and that is to substitute a radical for a conservative operation, and to remove the uterus. Such a course reduces the mortality very markedly. Williams records 56 cases with a mortality of 1.8 per cent. It is, however, a high price for a young woman to pay.

Perhaps if it was possible to get into the mind of the operator who unnecessarily resorts to Caesarean section late in the second stage that his duty is to remove the uterus as well as the infant, it might induce him to try obstetrical methods of delivery before resorting to surgical ones.

I think we may take it as a fact that every case in which an unforeseen Caesarean section has to be done for obstructed labour is directly due to a failure of diagnosis—that is, in the great majority of cases, to insufficient or inefficient ante-natal care. I do not mean to suggest that diagnosis is always possible. Theoretically it may be. Practically it may not. I think, however, that if the causes of obstruction that cannot be recognized before or at the beginning of labour be examined it will be found that the correct treatment for most of them is not Caesarean section. Ante-natal care and diagnosis is one of the surest ways of avoiding unnecessary operations, of enabling us to do the necessary ones at the proper time, and so of reducing the mortality to a fifth of what it would otherwise have been.

I am quite sure that it is customary in many places to practise in contracted pelvis what is called the test of labour and, if delivery fails, to perform a Caesarean section late in labour. I cannot give a general approval to such a course. In the first place, careful examination and internal measurement with Skutsch's pelvimeter will usually enable us to decide whether Caesarean section is the proper course to adopt, while, if there is a reasonable prospect that the patient will deliver herself and she fails to do so, pubiotomy is preferable, especially in multiparae. There are undoubtedly borderline cases in which an exact prognosis is impossible, and in such the obstetrician who attends them must decide according to his own views. I would like, however, emphatically to protest against the idea that a test labour can be substituted for exact preliminary diagnosis because the object of the latter is to exclude, so far as is possible, the necessity for the former.

The risks of Caesarean section do not end with the convalescence of the patient, because there is in all cases

the danger that a permanent injury may result to the uterine wall, which is thereby thinned and prone to tear during a subsequent labour. Theoretically, it should be possible to produce a union of the incision which after a short time, is indistinguishable in appearance or strength from the rest of the muscle. Practically, there is always the risk that unsuitable suture material, bad suturing, or sepsis of the wound may cause a weakening of the scar. That the risk is a real one is shown by Holland's collected statistics. Seventy women were delivered, or delivered themselves through the vagina after a previous Caesarean section, and in 18, or about 25 per cent, the scar ruptured during labour. Rupture during pregnancy is rare, but it, too, may occur.

Again, peritoneal adhesions, while they are not necessarily dangerous to life, and may be symptomless, are not an advantage. Williams, in forty-eight women who had been operated on in his own clinic, found subsequent "broad or dense adhesions" in one-third. In others who had been operated on elsewhere he found them still more frequently. Accordingly, a young woman on whom Caesarean section is done may be left in such a state that she is unable to have a normal labour subsequently, she may be rendered permanently sterile by the loss of the uterus, or she may lose her life from the risks inseparable from the operation. The obvious conclusion from these facts is that Caesarean section must be avoided whenever it is possible to do so. The three most common conditions in the treatment of which Caesarean section is most abused are probably the milder degrees of contracted pelvis, eclampsia, and placenta previa.

The milder degrees of contracted pelvis offer perhaps the largest field for the irresponsible operator. As Williams puts it: "I have been reluctantly forced to the conclusion that, in many parts of the country, the mere diagnosis of a contracted pelvis, irrespective of degree, is considered a satisfactory indication for the operation."

There are usually considered to be four degrees of contracted pelvis. In first pelvis whose true conjugate measures  $3\frac{1}{4}$  inches or more there is very seldom an indication for operation. When the conjugate measures between  $3\frac{1}{4}$  to  $2\frac{1}{2}$  inches, Caesarean section is permissible, but can be replaced by the induction of premature labour, or by pubiotomy. In the other two degrees Caesarean section is positively indicated. The vast majority of contracted pelvis fall into the first, or the upper limit of the second degree—Williams places it at about 95 per cent, and of these 80 per cent deliver themselves spontaneously. The selection of the correct line of treatment is entirely a matter of exact diagnosis, as made by internal and external measurement of the pelvis, and by estimating the relation of the foetal head to the pelvic brim. External measurement alone is valueless. A general practitioner who has not had a very large midwifery experience is most unwise to undertake the management of such cases, and the routine performance of Caesarean section does not lessen his responsibility. To the obstetrician whose experience entitles him to treat such cases I would like to say

"Learn how to use Skutsch's pelvimeter. There is no mystery about it. The ordinary mechanic learns to use measuring instruments which are much more difficult to handle. You can learn its use on the dummy almost as well as on the patient. It is usually necessary to give an anaesthetic, but the number of women who must be measured internally is very small. If it was a question of an ordinary gynaecological examination, you would not hesitate to give an anaesthetic if necessary. Why should you hesitate when the welfare, and perhaps the life, of both mother and child are at stake? It is necessary to exhaust all the powers of diagnosis before you advise your patient that a Caesarean section is unavoidable."

Eclampsia is probably the next most common cause of the abuse of Caesarean section, and that, too, in spite of the fact that its results prove it to be almost the most fatal line of treatment. I pointed this out at the Christchurch meeting of the New Zealand Medical Association in 1923, and a short time afterwards I met a medical practitioner who has a large obstetrical practice. He told me that he and a friend had listened to what I had said at the meeting, and that I think his words were—they had never laughed so much before. I suggested that it was unkind of him to have laughed at me. He replied, "We did not laugh at

you. We laughed at the idea of anyone doing anything, but the reason section for eclampsia." Let us see what it was he actually was laughing at.

Eeden in 1922 published an exhaustive analysis of the results of eclampsia as treated in Great Britain and Ireland. One of his conclusions was that both in mild and in severe cases Caesarean section and accompaniment force were followed by the highest mortality—a mortality which Holland found to amount to 3. per cent after Caesarean section.

Petersen found that in the United States the mortality of eclampsia radically treated was 34.8 per cent and Williams at Baltimore prior to 1916 treated by radical measures 65 cases with a mortality of 24.7 per cent.

In Germany Engelmann reported a mortality of 26 per cent and Lichtenstein a mortality of 16.7 per cent.

The results of conservative treatment on the other hand are given as follows. Williams was able to report a mortality of 13 per cent. Engelmann of 6 per cent and Lichtenstein of 9.4 per cent after they had changed round to conservative treatment. FitzGibbon and Solomonson reported 204 cases with a mortality of 10.3 per cent. Stroganoff collected 3,522 cases treated by his method with a mortality of 10.4 per cent while in more than 250 cases which he treated personally the mortality was 2.5 per cent. Incidentally I may say that he stated that the mortality in New Zealand was 2.2 per cent but I do not know where he got his figures. The statistics which I am just about to quote show a mortality of 22.9 per cent.

What my friend laughed at then seems to have been methods of treating eclampsia which reduced a mortality of between 16.7 per cent and 34 per cent in one of between 2 per cent and 13 per cent. Even in his own country of New Zealand facts are against him. I have recently analysed the results of 149 cases of eclampsia reported by different medical practitioners. Conservative treatment in 104 cases gave a mortality of 15.38 per cent. Caesarean section in 29 cases of 27.5 per cent, and accompaniment force and allied procedures in 16 cases of 43.7 per cent. I have no reason to think that the cases treated by Caesarean section were any more serious than those treated conservatively. It is generally recognized that there is a place for Caesarean section in the treatment of eclampsia but it is a very small one, and, practically speaking, is only to be found amongst the cases in which conservative treatment has failed to bring about any improvement.

Placenta praevia comes next and here too the results obtained from Caesarean section are compared with those of more conservative measures, are directly opposed to its routine use.

Holland reported that the mortality in the British Isles after Caesarean section in 139 cases was 11.5 per cent. R. W. Holmes estimated that the similar mortality in the United States was 20 per cent. On the other hand purely obstetrical treatment has given the following results. Williams who uses the Chamberlain-Hubbs bag had one death in forty cases or 2.5 per cent. Hofmeister, Behm, Lomer, Ess, Moller, Pinard and Strutz have recorded a total of 693 cases treated by Braxton Hicks' method with a mortality of 2.9 per cent. I recorded a short time ago 264 cases which had occurred at the Potomac Hospital with a mortality of 5.3 per cent. I am able to say that a number of the patients who died were moribund on admission and could not have been treated by Caesarean section. If the 264 cases are excluded as they should be in any comparison with the results of Caesarean section the mortality would have been about 3 per cent.

Unless we are prepared to accept obstetrical incompetence as a valid indication for Caesarean section the only justification for it in placenta praevia is that it will save more infants. As Holmes says, in the United States operation saved one baby for every mother it killed. I do not think that in ante partum haemorrhages the prospect of life posed by a premature infant weakened by maternal and often by foetal haemorrhage is sufficiently valuable to place in competition with the life of the mother.

There is a place for Caesarean section in the treatment of placenta praevia just as there is in the treatment of eclampsia but it is a very tiny one. A foetus that is viable and that has not been weakened by previous bleeding, a mother who is in good condition and a placenta which is central give I think, a good reason for doing Caesarean section in order to save the foetus.

There are still a few conditions left which serve as reason or excuse for Caesarean section. Malpresentation of the foetus is one of them. I think that since I was qualified I have known personally of two cases in which Caesarean section was done for transverse presentation. In one the mother died, in the other both mother and

child lived. The former was catastrophic, the latter—peculiar.

In the morning an hour and a half after the rupture of the membranes the medical attendant found a transverse presentation by external examination. He did nothing. In the evening he found the cord and a hand in the cervix. Internal examination. He gave the patient morphine. The next morning an incision was coming away, he did a Caesarean section. The patient was 24 and had had two normal confinements. His reason for his treatment was that the uterus was throughout in a state of tonic contraction but the fact that the child was alive and well twenty-four hours after the membranes ruptured is rather a cry to this. No attempt was made to see if the contraction would pass off under an anaesthetic or to correct the presentation by internal version.

I would make the following suggestions:

(1) That almost every case of neglected shoulder presentation in which the child is alive can be changed to a foot presentation by internal version.

(2) That if the presentation cannot be changed the amount of force required to bring the foetus out of the pelvis during a Caesarean section must be so great as to be injurious to the uterus.

(3) That such a case would almost invariably be a fact and that consequently a hysterectomy is always necessary.

(4) That when the child is dead there is no possible indication for Caesarean section.

I have the record of 209 cases of transverse presentation treated in the Rotunda Hospital. I do not think that decapitation has ever been done on a living child nor has delivery ever been effected by Caesarean section. In other words in every such case it has been possible to correct the presentation. I am of course excluding cases in which operation may be necessary not on account of the presentation but because the pelvis is contracted or other form of gross obstruction exists.

I said that there was a tiny place for Caesarean section in the treatment of placenta praevia. I do not think there is even this place for it in the treatment of transverse presentation.

Time will not allow me to discuss the other forms of obstructed labour that have been used as a reason or an excuse for Caesarean section. There are undoubtedly several forms in which the operation may be necessary and amongst them I am afraid that the tightness of the cervix is sometimes included. I had thought that this ancient legend of the obstetrician had passed away with the midwife who kept her fingers in the vagina throughout labour. Still should a bona fide instance of it occur I am inclined to think that it should be possible to remove it by obstetrical measures instead of removing the child by surgical ones.

#### Some Statistics of Results of Obstetrical Operations in Certain Maternity Hospitals

At the Pellicane and Associated Hospitals in New York 4,263 patients were confined. Caesarean section was done once in 37 cases. The death rate from eclampsia was .2 per cent and after Caesarean section 7 per cent. The total death rate was 25 per 1,000.

At the Boston Irving Hospital 1,133 patients were confined. An obstetrical operation was performed once in every 24 cases and Caesarean section was done once in every 12 cases. The death rate from eclampsia was .54 per cent and the total death rate was 22 per 1,000.

At the Jefferson Hospital in Philadelphia 1,453 patients were confined. Caesarean section was done once in every 63 cases the general death rate was 23 per 1,000.

With these may be contrasted the similar statistics of the Potomac Hospital for thirty-four years ending 1922. There were 57,432 confinements. Caesarean section was done once in every 366 cases. The death rate from eclampsia was .325 per cent and the total death rate was just under 5 per 1,000.

Is it any wonder that Williams speaks of "an abuse of the operation (Caesarean section) which can be attributed only to an obsession by the *furor operativus*?"

I do not think that the accuracy of the statistics I have given can be disputed. Assuming that they are correct, is it possible for anyone to advise the operation for conditions that can be equally well or even better, cured by obstetrical measure. Further, can anyone fail to recognize the necessity for such careful and rational examination of the patient as will enable us to operate under the most favourable circumstances whenever Caesarean section is really necessary?

There is a glamour which attaches itself to the operation of Caesarean section in the minds of the public and a kind of spurious fame. I am sure there is no need here to run against my attempts to encourage such absurdity, but perhaps it is well to suggest the wisdom of definite efforts to kill it. I know no better way of so doing than by medical men bringing their patients to recognize that, as I have said before, practically every case in which an unforseen Caesarean section due to obstructed labour is necessary is due to my rate theoretically—to insufficient or inefficient ante-natal care. Moreover, I am quite sure that, whether with or without medical guidance, the public will some day recognize the fact for themselves. It is entirely preferable, when this happens, that the medical profession should be able to say, "We told you so."

I have written a little strongly, but I think it will be seen that every opinion I have expressed is shared by obstetricians of the highest rank. I think, too, that many will agree with me that there is a real danger of obstetrics becoming a lost art. R. W. Holmes foresaw this danger ten years ago, and I do not know that it has grown any less since then. There are several ways of combating it, but this is not the time to discuss them. It is, however, a good time to remember that the conscientious medical adviser cannot justify himself when he tries to replace a lack of obstetrical knowledge by mere surgical facility.

I dislike very much bureaucratic interference with the liberty of the individual unless it is unavoidable, but voluntary co-operation would be most welcome. I think that if medical practitioners generally would furnish the Health Department with information regarding cases in which they found Caesarean section necessary they would materially help to check any abuse of the operation, and so to reduce maternal mortality.

#### Conclusions

Finally, I should like to summarize briefly the conclusions which I think must be drawn from the facts I have put forward.

1. Caesarean section done under the most favourable conditions is associated with a mortality of nearly 2 per cent, and may be followed by peritoneal adhesions, and subsequent rupture of the scar.

2. Caesarean section done under unfavourable conditions is followed by a mortality of from 10 per cent to 50 per cent, and in patients who survive the risk of after-complications is greater.

3. The only way of avoiding such operations is careful ante-natal diagnosis, and the only way of reducing their mortality when they are necessary is to remove the uterus.

4. Unless there is good reason for thinking that the uterine incision has healed satisfactorily, it may be unwise to allow a patient to deliver herself at subsequent pregnancies.

5. The treatment of eclampsia by Caesarean section is followed by a mortality of from 16 per cent to 34 per cent. Conservative treatment is followed by a far lower mortality.

6. The treatment of placenta praevia by Caesarean section is followed by a mortality of from 11 per cent to 29 per cent. Obstetrical treatment is followed by a far lower mortality.

7. The necessity for treating a transverse presentation by Caesarean section is almost unknown. When it occurs, it is also necessary to remove the uterus.

8. The statistics of hospitals in which Caesarean section is extensively done, unless they are based on a foundation quite distinct from that of other maternity hospitals, do not offer any encouragement to those who would imitate their practices.

Perhaps it would be wise to disarm criticism by admitting at once that my paper has not got a single new idea in it, or any promise or even suggestion of a new idea to come. It is more or less a plea for revision—revision to the older and saner ideas that used to govern a midwifery practice generally, and that still govern it in most places. If Truth lies in front of us, it is well to go forward, but if we have overshot her and she is behind us, it is

necessary to turn back. Discretion is the better part of midwifery.

## Memoranda;

### MEDICAL, SURGICAL, OBSTETRICAL.

#### MÉNIERE'S DISEASE TREATED BY THE ELECTROPHONIC

WHATEVER the true pathology of this disease, it presents a definite clinical entity, is extremely rare, and most distressing. First described by Ménière in the *Gazette Médicale de Paris* in 1861, the patient died, and the post-mortem examination revealed haemorrhage into the semicircular canals. Cases have, however, since been reported as having presented all the clinical signs of the disease in which post-mortem findings have failed to give evidence of haemorrhage into the canals.

A spinster, aged 43, consulted me early in April for severe vertigo and nausea. She was deaf in the left ear, hearing only a shout at one metre, the deafness was accompanied by tinnitus.

Her first attack occurred in August, 1926, when she fell to the floor from vertigo. She noticed that the left ear had become deaf after the attack. Consciousness was not lost nor has it ever been lost during the attacks, memory was, however, almost completely abolished. She was very dejected, the attacks of vertigo had become much more frequent both by day and night. The longest vertiginous attack lasted two hours, but the average duration was about half an hour. She had to crawl on all fours about the house and in going up and down stairs, in order to try and avoid an attack.

The trouble being labyrinthine, I at once began treatment with the Zund Berguet electrophonode. Within a week very definite improvement was manifest, and at the end of a fortnight she was able to attempt walking alone. Progressively with treatment the vertigo gradually disappeared, and with it the nausea. Now, after an interval of over two months, she has had no recurrence. Her deafness is better to the extent of hearing a low voice at one metre, the tinnitus is less, and memory has been regained.

I am confident that in the electrophonode otologists possess a very useful treatment in cases hitherto deemed hopeless, but its uses and limitations have yet to be defined.

ARNOLD FRIGUSON, F.R.C.S. Ed.,  
Aural and Ophthalmic Surgeon, Jersey General Hospital.

#### PULMONARY EMBOLISM FOLLOWING CHILDBIRTH

HAVING read the cases of pulmonary embolism following childbirth reported in the *BRITISH MEDICAL JOURNAL* of November 6th, 1926 (p. 835) by Drs McCulloch and Young and on November 27th (p. 987) by Drs Spencer and Dawson, and knowing such complications to be considered rare, I am sending you the report of a similar case which was under my care.

A young woman aged 30, healthy and robust (5-p.m.), had for some years suffered from varicose veins in both legs. I saw her on September 2nd, 1922. She was then in labour, with frequent slight haemorrhages. The cord was prolapsed and the implantation of the placenta low. As the cord was extremely pulsating and dilatation was occurring quickly, no intervention was attempted. She delivered herself in the course of an hour of a healthy female child. The puerperium was uneventful, temperature, pulse and lochia being normal. She was eating and feeling well and nursing the baby, and used to remark on my visits how well she felt. Never at any time did she complain of pain in the legs. She was sitting up in bed on the ninth and tenth days. After lunch on the eleventh day she was sitting up in bed, the nurse was putting on one of her stockings, when she suddenly complained of severe pain in the chest, and fell back in the nurse's arms. When I arrived she was livid with cyanosis, dyspnoea and air hunger, she died within fifteen minutes of the onset of the sudden pain.

No necropsy was performed, but I think no doubt could be thrown on the diagnosis.

Possibly pulmonary embolism following childbirth is not as rare as the textbooks would have us believe.

## Rebuclos.

### TO BEGIN WITH

THE stimulus which led Professor Raymond Pearl to write *To Begin With*, the subtitle of which is "Prophylaxis against Pedantry," was a doubt whether the results achieved by the "highly formalized and mechanized system of education which prevails in the land and is in such perfect accord with the cultivation of that efficient, standardized mediocrity which seems to be the very spirit and genius of American civilization" are wholly satisfactory. Professor Pearl is not the only doubter. "Our present difficulty," wrote an Oxford professor a few years ago, "is that our students often attain to technical dexterity without acquiring the mass of knowledge which is needed if their skill is to be profitably employed" (Watson's *Life of Bishop John Wordsworth*, p. 109). That was said of theological and philological research, but it is equally true of biological and medical work. Professor Pearl writes

"What I used to do was to make out lists of highly technical researches in the particular field of interest and tell the student that along that pathway was the road to salvation. This I am sure was a mistake. It started from a false assumption. The progression was forthwith to the effect on the supposition that the general has been taken care of. But nothing could be more ridiculous nonsense than such an assumption. In consequence of the widely prevailing pedagogical theory that needlework, jigsawing, salesmanship and many other kindred academic disciplines are of at least equal cultural and intellectual value in the training of our youth to the study of Greek or Latin or mathematics or chemistry coupled with the permission, if not active encouragement to the undergraduate to specialize during his mental infancy it results that when the young things begin serious graduate work a solidly grounded general background upon which to build a sound specialty is precisely what, generally speaking, they most completely lack."

Professor Pearl's remedy, or palliative, is to bring to the notice of his students books which are either essentially great literature or, at least, illuminate some aspect of human life and work (or play) which is not a mere returning subject of academic education. It is unlikely that any two men would approve the whole of Professor Pearl's list, it is still less likely that any educated man would object to the inclusion of a very large majority of the items, and we hope, but do not much expect, that young men and women turning out the es for the degree of Doctor of Philosophy will not only read Professor Pearl but take his advice. For indeed, although Professor Pearl writes easily and wittily about it, the evil which he sees is a very great one. At least no medical journalist will underestimate it. Every year hundreds of papers are published on a level of technical efficiency which was not attained a generation ago by any writers or only by writers of the greatest ability. But the general value of these papers in an intellectual sense is greatly below their technical standard. We would even go so far as to say that while the best papers now printed are as good as or better than the best printed fifty years ago, much more pure nonsense—more both absolutely and relatively—now finds its way into print than in the past. The reason is, as Professor Pearl contends, that we are producing not educated human beings but technicians. In 1848 Macaulay made this entry in his diary

I received to-day a translation of Kant from Ellis's friend at Liverpool. I tried to read it but found it utterly unintelligible just as if it had been written in Sanscrit. Not one word of it gave me anything like an idea except a Latin quotation from Persius. It seems to me that it ought to be possible to explain a true theory of metaphysics in words which I can understand.

We may conceive the scorn with which our young post-graduate philosophers would smile at so philistine a demand. Metaphysics and medicine we shall be told have progressed so far that nobody can hope to understand the description of any research within their fields without prolonged technical training and, as everybody cannot be technically trained in every branch—even of his own profession—it would seem to follow that we must all be

mutually incomprehensible. Perhaps this is true, but there is another hypothesis which covers this fact. It is that young people are now so poorly educated that they can no longer express themselves in what was once the common speech of cultivated men, and take refuge in jargon. The dean of the faculty of letters of Paris—quoted by Professor Pearl—complains that

"in the papers on my desk are lines that are ridiculous. If they were published they would be taken for the invention of a humorist. In a single page of Latin we commonly find a dozen examples of bad spelling. We don't write French any longer because we don't speak it. That's the whole difficulty."

Perhaps there is no remedy. It is so hard to earn a living that very few people can afford to look upon education as something more than a means toward a pecuniary end, and that sort of education is technical education. Still, perhaps something may be done by calling the attention of our post-graduate to good books. Professor Pearl may possibly save a few souls and even save the world from a few doctoral theses.

### THE HISTORY OF BCG

Whatever may be the outcome of Professor Calmette's work on the bacillus Calmette-Guérin (BCG), there can be no doubt that his researches and theories are ingenious and interesting. Criticism of this sort is far from being purely what of the destructive variety, alleging, for example, that the statistics are insufficient, no properly controlled or unconvincing. Professor Calmette has now published, in collaboration with Dr. Guérin Boquet and Négre, a summary of his researches in a volume entitled *La Vaccination Préventive contre la Tuberculose par le BCG*.

The argument of the book is that in tuberculosis immunity—meaning thereby resistance to reinfection—only exists when the body harbours some living elements of the parasite, and that when the lymphatic glands are infected by a few slightly virulent bacilli the individual is pre-immunized against virulent infections. He quotes J. Parrot of Nancy as stating that in tuberculous families 40 per cent of infants under 2 years of age, and 50 per cent between the ages of 4 and 10, react to tuberculin while in non-infected families, although there is no reaction in children under 2, 31 per cent react at 10 years of age.

The first part of the book before us is devoted to an examination of various attempts that have been made to discover a method of antituberculous vaccination. The attempts appear to show that it is impossible to produce immunity by means of dead bacilli. Experiments with different varieties of bacilli, sometimes modified by various physical or chemical agencies, have suggested that antituberculous vaccination might be efficacious if living bacilli, deprived as far as possible of their aptitude to produce extensive follicular lesions, were used. It was on these lines that Professor Calmette began, about 1903, to experiment with the bovine bacillus.

The second part of the volume describes the experimental study of the BCG. Having arrived at the conclusion that in cattle lasting tolerance of tuberculous infection required the presence in the animal of living bacilli, and seeing that the bacilli in the glands should be incapable of producing tuberculous lesions, Professor Calmette and his collaborators tested the efficacy of pre-immunization by the intravenous injection of the BCG in cattle kept in contact with infected animals. They found the method entirely satisfactory, but the duration of protection did not exceed eighteen months. Incidentally they formed the opinion that a positive tuberculin reaction could not be considered as a criterion of infection, but as a criterion of immunity. Consequently they consider that it loses all diagnostic importance, inasmuch as when everybody susceptible to tuberculosis has been artificially impregnated with avirulent bacilli, they will all react in the same manner as infected subjects.

According to Professor Calmette the immunity is exactly analogous to that produced by other living attenuated virus-vaccines, such as vaccinia, the enteric vaccine, and

<sup>1</sup>*To Begin With*, being *Prophylaxis against Pedantry*. By Raymond Pearl. New York and London. A. A. Knopf. 1927. (Cr. 8vo pp. 86. 5s. 6d.)

<sup>2</sup>*La Vaccination Préventive contre la Tuberculose par le BCG*. Par A. Calmette avec la collaboration de C. Guérin, A. Boquet et L. Négre. Paris: Masson et Cie. 1927. (64 x 94, pp. 250. 40 figures. 25 fr. sans majoration.)

that for hydrophobia. As with these vaccines, the immunity only lasts for a comparatively short time. The sole difference is that it is difficult to apply the BCG to adult subjects because so many are already infected by virulent bacilli. Hence the need for using the BCG in the early days of the individual's existence.

After his experiments on cattle and on rabbits, Professor Calmette obtained a trial of his BCG by Dr. Wilbert on a series of monkeys in French Guiana. These monkeys were immunized either by a single subcutaneous injection or by five ingestions by the mouth. The pre-immunization lasted at least a year, and could be renewed by fresh ingestions yearly.

In the third section of his book Professor Calmette describes the preparation of his cultures, the physical and chemical characters of the BCG, and the histological changes associated with its injection. One milligram of BCG suffices to produce tuberculin sensitivity. But Dis. Boquet and Negro have established that immunity and tuberculin hypersensitivity are distinct and independent states in organisms infected by the Koch bacillus. Immunity comes later than hypersensitivity. In many cases the extinction of tuberculin sensitivity is not accompanied by any lessening of the resistance to reinfections. Although in many animals a large dose of BCG may cause the internal organs to be studded with follicles or tubercles, these follicles never caseate, and in process of time completely disappear.

The last part of the book is devoted to the methods and results of administration of BCG to infants, and it is against this part of Professor Calmette's work that criticism has mainly been directed. The justification for this criticism is perhaps to be found in the chronicity of tuberculosis, the time required for watching and comparing patients, and the ease with which patients disappear from view when long periods of observation are necessary. Thus, although many thousands of infants have now been pre-immunized in France, the statisticians who have examined the figures have only been able to deal with a small proportion which have been definitely followed up. M. Moine reported on 882 cases treated in the course of two years and seven months. Dr. Ott dealt with some 332 cases in the department of Seine Inférieure and Le Havre. Dr. Briand studied 1,877 cases of pre-immunized infants, but whether this number included one, both, or neither of the two other groups is not clear.

It is evident that the time has not yet come when a definite opinion can be given on the pre-immunization of infants with BCG. But it is equally evident that the work of Professor Calmette and his colleagues cannot be passed over without investigation. Professor Calmette's proposition is that the only way to produce immunity to tuberculosis is to provoke a state of what he calls pre-immunization during the first days of life, to ensure as prompt an impregnation as possible of all the lymphatic organs with a sufficient number of bacilli to form a true vaccine, and to see that these bacilli are deprived of virulence and at the same time capable of producing defensive substances. He thinks that BCG meets these requirements. But he admits that against intrauterine infection by the so-called tuberculous ultra-virus, investigated by A. L. Calmette, and others, BCG may fail to operate, and that it may form an insufficient protection against massive infections. The case is presented in an interesting manner in the book.

#### FORENSIC PSYCHIATRY

*An Introduction to Forensic Psychiatry in the Criminal Courts*, by Dr. NORMAN EAST, is a book which fills a gap in forensic literature. Of recent years much attention has been paid to the mental condition of persons accused of crime and whilst there is no scarcity of books dealing with psychiatry, these treat the question of mental disease from the medical rather than the forensic aspect, a distinction which, unfortunately, mental experts sometimes fail to appreciate. Dr. East before his appointment to be

medical inspector of prisons, was for many years senior medical officer of Brixton Prison, and in that capacity had a very extensive experience in this branch of forensic work. The results are embodied in his book, which discusses some of the same subjects as the late Dr. Sullivan's *Crimie and Insanity*, reviewed in our issue of June 28th, 1924 (p. 1151). Dr. East has had the advantage not only of dealing with insane criminals, but of having under his care persons with regard to whom the question of insanity has been raised but not admitted by the courts. This has afforded him much material, and the chapter on criminal responsibility, a subject bristling with difficulties, is written in an extremely clear and interesting manner.

We do not know of any work which gives such an excellent summary of the matter. Certifiable insanity and a condition absolving an accused person from legal liability are by no means the same, as the author points out, a fact which may at first mislead a medical witness. It does not follow that because a person charged with an offence is found to be insane that he should be certified, or that because he is certifiable he is not responsible for a particular crime. The question of certification frequently presents difficulties in forensic practice, and has lately become so prominent, owing to the number of actions against medical men, that many practitioners are unwilling to accept responsibilities in this matter, as every police surgeon is aware. The inclusion in the next edition of a chapter on certification would add to the value of a most excellent work. The book is clearly written and well illustrated with cases, a point of great value in forensic work. It will make an appeal not only to the mental expert but to all engaged in criminal cases.

#### NEURO-PSYCHOLOGY

*Thought and the Brain* is the title of a translation from the French of a valuable monograph by Professor HENRI PIERON. The author, who is the editor of *L'Année Psychologique*, has made a number of notable contributions to neuro-psychology and is a distinguished and erudite writer. The ideal of science, he observes in his preface, is the highest possible degree of unification, and certainly as far as the problem of body and mind is concerned it undoubtedly aims at the correlation of psychological facts with physiological mechanisms. This view would appear to be sound, as also his contention that, whatever certain theorists may say to the contrary, neuro-physiology does often provide an adequate representation of the laws established by psychology, whereas the study of the functions of the brain frequently supplies a satisfactory explanation of psychological phenomena. The validity of such views is made abundantly evident throughout this book, which provides an excellent critical survey of modern opinions regarding the functions of the nervous system.

The book is divided into four parts. In the first an outline of our knowledge of neuro-mental functioning is given, a lengthy chapter being devoted to the problem of localization or the differentiation of function in the cortex. In the second part are considered the receptive and motor functions—the elementary modes of sensorimotor thought. The third part deals with verbal function and thought—the cerebral mechanism of language—and with aphasia. The author gives an admirable presentation of this most difficult problem. The final section is concerned with the effective regulation of mental action, both its role and mechanism being briefly considered. The reader will probably wish that these concluding chapters had been considerably expanded in view of the importance of their subject-matter for our understanding of normal and abnormal behaviour.

This book will interest the practising physician, the neurologist, and the psychiatrist. Mr. Ogden, who has translated it, has done a service to English-speaking readers by introducing the work of a writer who has much to say to communicate.

# PHYSIOLOGICAL CHEMISTRY

THE vitality of the study of biochemistry in the United States and presumably, the dissatisfaction with its teaching is testified by the number of new textbooks of the subject which continue to come to us from across the Atlantic. Some have been so bad as to have established no reasonable excuse for existence. Others have been of sufficient merit to be welcomed without reserve if without enthusiasm. Not one—if we may be so rash as to seek to identify the classic in contemporary literature—has borne those evidences of inspiration which would place it beside the older masters whose teaching “shall not grow old.”

The latest arrival is *Introduction to Physiological Chemistry* by Professor MAYER BONANSKY. While it is unlikely to achieve the most favoured place in the library of the teacher it is certainly not to be classed amongst the bad books. The author's plan is conventional. Indeed, tradition and rigid curricula make it difficult for a textbook to attempt an original approach to the subject. The account given of the chemistry of carbohydrates, fats, and proteins is followed by digestion, enzyme action, and putrefaction. The chemistry of the blood and lymph next invite attention and then discussion is directed to inter-meat metabolism, the urine, and the internal secretions. The volume concludes with chapters on animal calorimetry and nutrition. These are on the borderland of biochemistry and physiology and are often but poorly handled in such books as this. In this instance however they definitely embellish the work. These physico-chemical principles which have thrown light on many characteristics of protoplasm and many intricacies of function have been introduced where they aid precision but have not been laboured to the point of wearing the biological student uncomfortable in the company of mathematical formulae.

Within the limitations of detail which the author has imposed upon himself the book is comprehensive and coherent and offers a nicely balanced survey of a field whose borders touch the territories of many sciences.

## NOTES ON BOOKS

THE second number of *Antiquity* a quarterly review of archaeology, edited by Mr O. C. S. CRAWFORD is as good as the first in particular the standard of illustrations—an important part of a publication of this kind—both in the text and on special paper is well maintained. It contains an article by Professor A. H. SAVILE on the Arvan problem with a subtitle fifty years after—after that is his early writings about the Aryans and the Hittites. A great many facts have been collected in the interval. Professor Savile still hesitates to generalize but he says that it has proved that there was continuity of culture and trade, possibly also of language or race or both between north-western India and the valley of the Euphrates at the very beginning of the Bronze Age. An article by Dr E. A. HOOTON “Where did man originate?” is also wisely inconclusive but he goes so far as to reject the theory of a central Asiatic area of dispersal for the protohuman stocks. The annual subscription payable to Mr Crawford, Nursing Southampton is £1. Separate numbers can be obtained from Mr John Pellows, Gloucester price 5s. 6d.

In preparing their book on the *First Principles of Chemistry* DOORSON and BERRY have evolved a scheme of presentation founded on their own appreciation of those principles. This is in contrast to many introductory textbooks which have been prepared on the plan of making an older book more modern by adding newer discoveries. Such books usually have all the defects that result from putting new cloth upon an old garment. The authors of the book before us have revised the facts of chemistry and the reactions which typify general principles in appropriate connexion with their relation to modern theory. Our appreciation of the book is so high that it seems worth while to mention one or two of the few imperfections we have found. The formula  $\text{Na}(\text{SiO}_3)_2$  (p. 42) is not correct and may prove misleading. There can be no objection to writing  $\text{Na}_2\text{O}(\text{SiO}_3)_2$  nor should there even be any prejudice against

the expression  $\text{CaO} \cdot \text{SiO}_2$  for  $\text{CaSiO}_3$  where it suits the context. We suggest too that the sentence (p. 121) “When heated with caustic alkalis sulphur passes into solution in the form of the metallic sulphide, might be enlarged to show that a part of the sulphur forms sulphide while another part enters into the composition of an oxyacid thus behaving like phosphorus, chlorine, and other non-metallic elements. The learner who works conscientiously from this little volume will lay a sure foundation for all that he may afterwards need to build.”

The nursing profession is already well supplied with textbooks on midwifery but Professor THORNTON has the right to say “I would like to see a book which would deal with the normal midwifery for Midwives and Nurses.” The book embodies a course of lectures given to the nurses at the Bournemouth Hospital and deals almost exclusively with the normal process of parturition. The main principle of the book is that midwives should understand clearly what is normal so that they may be able to help in every case showing abnormality. He forbids them in any circumstances to make vaginal examination and urges the adoption of a rectal examination in the few cases where abdominal palpation does not lead to satisfactory diagnosis. Such a reference only is made to common abnormalities such as breech and hinder presentations. The author maintains that the nurse's duty ends when he has ascertained that the case presents difficulties but the country midwife ought to know the immediate treatment of the commoner complications pending the arrival of medical help which he should be able to do. In the management of the third stage of labour the nurse is advised to leave the uterus severely alone. To quote the author's words: “Think of the uterus as a hot roughly hot tempered irritable old woman with a gun.” The chapter on a physician's midwifery is misleading for surely blue and white physicians are not the same nor is the treatment identical for the two varieties. A short chapter on aphorisms is included but for a convincing physician's ideal is to present a full book of normal midwifery but it is probable that this fuller reference to the abnormal would be desirable and that while the book is hardly adequate for a nurse or a physician of following with intelligent interest all the cases which may come under his care.

Dr I. F. HUNTER's monograph on gynaecology in the *Corpus* and *Pliny* which is dedicated to the sixth international congress of the history of medicine recently held in London and Amsterdam (see JOURNAL, August 20th 1927 p. 317) is divided into two parts devoted to a treatment in obstetrics and gynaecology respectively. In his introduction Dr Hunter points out that the classical and archaeological writings contain a mass of material on drugs and surgery in the ancient schools. It could not be difficult to form collections on the evolution of the gynaecology of that time in the present day from a study of a general textbook on pharmacology. Both *Diocorides* and *Pliny* quote extensively from older authorities but while *Pliny* was a conscientious if extremely credulous and egoist physician *Diocorides* was a medical practitioner who has left a somewhat more critical and systematic work probably based on his own experience. Although there was an interval of more than four centuries between the *Corpus Hippocraticum* and the age of *Diocorides* and *Pliny* gynaecology and obstetrics did not undergo any essential advance in the interval. The names of diseases were about the same the symptoms were not more closely defined and drug treatment at follow of the same lines in the first century A.D. as in the age of Hippocrates.

In *New Poems and a Preface*, Mr HERBERT MOORE PIM who is not a member of the medical profession contributes some Hospital Lyrics dated last year from the Cromer Cottage Hospital and in a footnote appeals for more generous support than our hospital has now received. In a number of smoothly phrased sonnets he pokes playful fun at the medical men who appear to have ventured to explore his chest at the ways of matrons and at the nurses who trade his bed with more or less success. His gratitude is more outspoken to one specially, to—

Doctor may have a heart of stone  
The Dentist's heart is like your own  
In fact he has such tender ears  
He cannot hurt you if he tries

The preface dated this year from Kelling Sanatorium, Norfolk, deals in rather pathetic tones with the fate of poets.

## THE STATE OF THE PUBLIC HEALTH

## SIR GEORGE NEWMAN'S REPORT FOR 1926

ENGLAND AND WALES

[First Notice]

In his annual report, which has now been issued,<sup>1</sup> Sir George Newman deals with the state of the public health in England and Wales during 1926. The statistics on which it is based are the Registrar-General's returns relating to births, deaths, and infectious diseases, together with the various records in respect of invalidity obtained through the operation of the National Health Insurance Acts. Supplementary data have been derived from the reports of medical officers of health, and from investigations by medical officers of the Ministry of Health and other governmental departments concerned with the well-being of the people.

This year's report is appreciably larger than the previous one, it contains twelve chapters and four appendices. A prominent feature is the emphasis laid on the danger of drawing erroneous conclusions from statistics, particularly when the original returns cannot be regarded altogether without suspicion. When this primary information is incomplete or inaccurate the deductions drawn will have a similar character.

*Registration of Causes of Death*

An example of this is furnished by the official recording of deaths, from which much information about the incidence of ill health is necessarily derived. The accuracy of death certificates and the findings of coroners' courts have consequently a collective importance which is not always fully recognized. Sir George Newman believes that the official records of mortality contain actual errors due to the omission of relevant information, either deliberately or because it was unobtainable. Thus he suggests that if the mileage of motor vehicles was known and taken into consideration it might be found that this was relatively less dangerous year by year, though the absolute danger to life in this respect is increasing rapidly. Moreover, tabulation of these accidents by localities might reveal facts of considerable significance, and it is not stated what proportions of the victims were drivers, passengers, and pedestrians. In the case of deaths due to cancer of the liver and gall bladder there is often failure to intimate the primary site of the disease, and it is considered that when such an operation is complete removal of the breast for carcinoma has been performed and the patient dies subsequently of cancer elsewhere in the body, this previous event is sufficiently significant to require its being recorded on the death certificate. The omission of relevant information assumes a special importance in the case of deaths attributable to alcoholism, and Sir George Newman devotes attention to this obvious cause of false deductions. He compares unfavourably the present system of open certification with the practice in Switzerland, where the certificate is a confidential document, and the friends of a deceased person have no access to the statement of causes of death. He does not suppose that the records in this country are thereby absolutely vitiated, and thinks that the conclusions drawn annually as to the decline in intemperance are probably substantially sound, but he believes that there would be a considerable extension of knowledge as regards the real toll taken of human life by the intemperate use of alcohol if death certificates became confidential documents. Similarly the sensational index afforded by the number of children suffocated in bed or "overlaid" by adults is open to suspicion when used as evidence of alcoholism; other factors might conceivably become more prominent if greater care were exercised in certification. Sir George Newman also draws attention finally to the unsatisfactory term "status lymphaticus," and in a careful examination of the problems concerned, describes its employment since 1911, when it was first used as a heading in the publications of the Registrar-General. He insists that the using of a diagnosis on the weight of the thymus is unscientific owing to the marked variability of this gland, not in the present state of knowledge,

can the histological appearance be used safely as a criterion. He believes that status lymphaticus is a mere verbalism, and that the current textbook teaching on the subject is erroneous; he goes so far as to use the terms "medical mythology" and "obscure intusism" in this connection. He concludes that it is urgently necessary to ensure correct registration of the cause of death since, apart from social and legal issues, it supports the fabric and vit of preventive medicine. Sir George Newman's careful examination of this question will draw attention anew to the provisions of the Births and Deaths Registration Act, 1926, which came into force last July, and it may be recalled that some account of the reforms introduced, particularly in respect of death certification, appeared in our issue of June 18th (p. 1118).

*Births and Deaths*

The birth rate has again declined, the fall in 1926 being 0.5 per 1,000 of the population as compared with the rate in 1925, and 7.7 under that for 1920, which marked the climax of the temporary rise in the birth rate following demobilization. The death rate similarly fell, being 0.6 per 1,000 less than in the previous year; it is now approaching the rate in 1923 (11.6), which is the lowest on record. A slight upward trend in the mortality rate is expected to occur soon, this is believed to be inevitable owing to the change in distribution of the age groups, for a declining birth rate implies an increase in the average of the population. It will not necessarily indicate any strengthening of the conditions favouring mortality.

The following causes of death were prominent during 1926, the figures in each case being the proportion in 1,000 deaths: diseases of the heart and circulatory system, 188, bronchitis, pneumonia, and other respiratory conditions excluding tuberculosis, 150, malignant diseases, 117, affections of the nervous system, 103, and all forms of tuberculosis, 82. Increases were recorded in the deaths from diphtheria, cancer, and diseases of the heart, but these were more than counterbalanced by a decline in the deaths from influenza, pneumonia, bronchitis, and the diseases of early infancy. The reduction in the infantile death rate affected mainly the age-period 3 to 12 months, the mortality under the age of 4 weeks still remains relatively high. Whooping cough was a serious factor, but there was a decline in the number of deaths from influenza. The low level of infant mortality in 1926 may be reckoned as the equivalent of the saving of some 40,000 infant lives. It also implies that the physical condition of children between the age of 1 to 5 years has improved, and that hygiene, both personal and public, is better. The mortality among women in childbirth remains high, in 1926 2,850 women died, puerperal fever accounting for as many as 1,109.

*Small-pox*

In 1926 in England and Wales 10,141 cases of small-pox occurred as compared with 5,354 in 1925, 3,797 in 1924, and 2,504 in 1923. The disease was for the most part mild in character and confined to the northern parts of the country. The 5,354 cases of small-pox in 1925 were scattered through twenty-two counties, only fourteen being so affected in 1926, those with the highest incidence were Durham (6,645 cases), the West Riding of Yorkshire (1,215), Derbyshire (882), and Northumberland (843). The disproportionate prevalence in Durham is attributed to the operation of various factors, thus there were reported invasions of the disease from Northumberland, two districts were backward in taking active measures to limit the spread of infection, and it was difficult to obtain a adequate number of beds for isolating the patients. Reference is made to the outbreaks in London and the Willesden urban district to indicate how easily the infection of small-pox may be introduced into England. Sir George Newman comments briefly: "It must be quite plain, that the facts and figures recorded indicate an increasing tendency to small-pox, and the English people must make up their minds whether they prefer small-pox to vaccination." He adds also in the report that in the world generally the incidence was low in 1926, the only European countries in which more than 100 cases were reported during the year.

<sup>1</sup> *On the State of the Public Health. Annual Report of the Chief Medical Officer of the Ministry of Health for the year 1926.* H.M. Stationery Office. (Med. 810 pp. 221 3s. net.)

England, France, Italy, Spain, Portugal, and Russia. There was, however, marked prevalence in Egypt and Algeria, and an epidemic with over 2,100 deaths at Rio de Janeiro, while 957 cases with 171 deaths occurred between January 1st and May 15th, 1926, at Los Angeles.

#### Various Infectious Diseases

During 1926 were notified 2,739 cases of enteric (including paratyphoid fever) as compared with 2,779 in the previous year, 4,121 in 1924 and 3,211 in 1923. Scarlet fever cases fell to 81,672 from 91,362 in 1925. Sir George Newman expresses the hope that the early administration of scintillated antitoxin serum in suitable cases will reduce materially the period of detention in hospital of these patients. There were 51,669 cases of diphtheria notified in England and Wales during 1926 with 2,094 deaths, as compared with 47,720 cases in 1925, and 41,680 in 1924. The warning is given that immunization is too often postponed unduly until an epidemic occurs, full protection cannot then be assured, owing to the fact that the condition of immunity requires at least two or three months for its development. The diphtheria death rate increased slightly from 0.071 per 1,000 population in 1925 to 0.077 for the year under review. Until the end of 1926 there was no evidence of influenza being of particular importance statistically, but in the first week of January, 1927, an epidemic began in London and moved slowly northwards. Sir George Newman gives an account of this epidemic, and concludes that the recrudescence of influenza was rather more serious than the outbreak in 1924, but less so than that of 1922. In age distribution and general type its features were those of the pre-epidemic period rather than of 1918-19. There was an associated increase in pneumonic notifications. Two locally contracted cases of bubonic plague occurred in Liverpool in 1926 but the cause was not traced. One case of typhus of unknown origin was detected in Sunderland.

#### Acute Poliomyelitis

Special consideration is given to acute poliomyelitis in view of its increased prevalence during 1926, when 1,159 cases were reported with 176 deaths. The outbreaks since 1897 in various parts of the country are tabulated. In 1926 the disease began its epidemic phase in the middle of July, and continued till the end of the year, extending through the mild winter, including the first two months of 1927. The disease was particularly prevalent in Essex, Kent, and the Midlands but the cases were not very numerous in the most populous areas, and in London the incidence was relatively slight. The infection usually involved small groups of population in rural districts. Details are given of the outbreaks in Leicestershire, Essex, and Kent. It is concluded that there is at present no evidence to incriminate the milk supply in this connexion. No social predilections were shown by the disease, and it appears that the home conditions were not so concerned in its spread as they are in other contagious diseases. Clear evidence of contact transmission was obtained in two outbreaks, and it seems to be established that the infection may be conveyed by persons suffering from acute typical attacks, or from the mild and atypical forms; it may also be spread by healthy persons who have come into contact with the diseased without being affected by it, or by chronic carriers who have apparently recovered fully. The infectivity in acute cases is greatest during the early stages of the malady. The possibility of transmission by insects, food, dust, or sewage seems to be remote and human contact remains the chief, if not the sole, probable means of spread. The general evidence points to an incubation period of four to five days though shorter and also much longer intervals have been recorded. Details are given of the clinical manifestations, the diagnostic criteria and the prevention and treatment of the disease. Sir George Newman concludes that infection is probably widespread in a community during an epidemic, but that only a small proportion of susceptibles are attacked. He emphasizes the importance of early diagnosis and of providing institutions equipped to give special treatment with a view to preventing muscular weakness or permanent deformity.

(To be continued)

## BRITISH ASSOCIATION FOR THE ADVANCEMENT OF SCIENCE

### ANNUAL MEETING IN 1926

THE annual meeting of the British Association for the Advancement of Science, which was founded ninety-seven years ago, began in Leeds last week when Sir Arthur Keith, M.D., F.R.S., Conservator of the Museum of the Royal College of Surgeons of England, succeeded the Prince of Wales in the presidential chair. The Prince, who was still in Canada at the time of the meeting, sent a message in which he recalled that in his address at Oxford last year he had dealt with the relations between science and the State. The choice of this topic had, he thought, been justified by the proceedings of the Imperial and Colonial conferences, which both had emphasis upon the value of scientific research in relation to imperial development, and both set up special committees on research. Such events put it beyond doubt that one of the main objects of the British Association was in process of achievement—namely, that of 'obtaining more general attention for the objects of science.' The Prince then referred to the splendid generosity of Sir Alfred Arrowood in making a gift of £10,000 for the general purposes of the Association, to be expended in the course of twenty years. In conclusion, the Prince said that he could wholeheartedly congratulate the Association on its choice of his successor for Sir Arthur Keith's name stood very high in the science of man's origin and early biological history.

Before Sir Arthur Keith began his address he read out a letter of thanks to the Prince of Wales, in which, also, stress was laid on the inspiring message the Prince had given at Oxford to the Association, and through it to men of science throughout the Empire. His appeal had already borne fruit. Closer union between men of science overseas and their colleagues at home in their endeavour to solve problems of imperial concern was within sight.

The President then delivered his address, which is printed at page 459. In acknowledging it its conclusion a vote of thanks which was given with great enthusiasm, Sir Arthur Keith announced that the Council of the British Association was considering the advisability of purchasing for the nation the house and surroundings in which Charles Darwin worked and which were thus the cradle of ideas that had transformed the outlook of man.

### THE SECTIONS

The British Association publishes at the time of its annual meeting a *Journal of Scientific Transactions* which not only serves as a *Journal* of the various meetings, but also gives concise abstracts of many of the papers. The publication is of interest also in affording some idea of the all-embracing scope of science. From the nucleus of the earth to infinite space there is hardly a phenomenon of the universe that escapes its scrutiny. The approach, naturally, to the man of science but the ordinary citizen, in these strenuous and somewhat perilous times, cannot be so indifferent to such subjects as for example, mental stress and the psychology of accidents.

### HUMAN PHYSIOLOGY: ITS STUDY AND TEACHING

Taking for the subject of his presidential address the development of human physiology, Dr C. G. Douglas, F.R.S. (Oxford) sought to place before the members of the Section of Physiology a picture of the real task of physiology—namely the study of the phenomena which characterize normal life as shown in the individual organism. Bearing this definition in mind it was clear that the very great advance in knowledge which had been made in the last fifty years did but take us to the threshold of the subject, investigation had been analytical the organism had been treated as consisting of more or less independent systems—circulatory, respiratory and other—which were separately investigated in detachment, as it were, from the individual organism and studied apart from their normal setting. Moreover, the discoveries, with some exceptions, had been made in animals by experimental methods, and often under the influence of anaesthetics—

that is to say, not under normal conditions, but under the pathological conditions of traumatism and intoxication. Invaluable as the information reaped from these researches had been, it did not meet the demands of the definition, nor give the full answer that we required. In a few instances the experimental procedure had been of a nature not to interfere with the regular bodily functions of the animal, this was so, for example, in Pavlov's researches on the digestive juices and those of Rubner on nutrition and energy liberation. Apart from these exceptional instances, however, it could hardly be denied that the traditional methods had their limitations, and Dr Douglas contended that in the study of normal physiology man himself was in many instances a far more advantageous subject for investigation than were the lower animals. In support of this contention he adduced several instances in which valuable information had been reaped from investigations on the human subject, and he claimed that for gaining any adequate conception of what is really implied by life, the method could be replaced by no other.

The history of the development of our idea about respiration afforded, he said, a striking example of the value of human physiology. The researches of Haldane and Priestley by this method had shown that the activity of the respiratory centre depended on its sensitiveness to the concentration of CO in the blood—a trifling rise causing hyperpnoea, a trifling fall causing reduction or cessation of breathing. It became evident that the activity of the respiratory centre was proportional to the mass of CO produced in the body and carried to the lungs, and this in turn implied that the quantitative correlation of the ventilation of the lungs with changes of metabolism in the body as a whole was ensured by chemical means. From this work we gained our first insight into the amazing delicacy of true chemical correlation within the organism. It was subsequently recognized that the respiratory centre was sensitive not to CO<sub>2</sub> is such, but to changes in the H-ion concentration of the blood, and that lactic acid accumulation resulting from muscular activity had to be taken into account. Having grasped the fact that breathing was automatically adjusted to tissue metabolism, it became obvious that the delicate adjustment of the breathing in conformity with the various changes in the activity of the different tissues and organs would be valueless without an equally delicate coordination of the circulation, since on this depended the transport of gases between the tissues and the lungs.

To ascertain the full facts of the regulation of the circulation and its adaptation to the varying needs of the body was a more difficult problem than the regulation of breathing, but a beginning had been made. Methods had been developed for determining the circulation rate in man, for measuring the variations in the amount of blood expelled from the heart under different conditions of bodily activity, the extent of the changes in gas content of the venous blood entering the lungs, and the relative part played by alterations in the pulse rate and in the systolic discharge at each beat. These and other researches referred to by the lecturer showed something of the part that human physiology had already played in the study of vital phenomena. The evidence of balanced interaction of the functions of the different organs with the preservation of the functional integrity of the whole, which was so convincingly brought home to us in experiments on the human subject, had made us appreciate the fact that for the comprehension of life it was the normal human organism which should be regarded as our physiological unit.

Finally Dr Douglas expressed the opinion that the teaching of physiology would be more satisfactory if human physiology occupied a more prominent position, not so much as regards advanced teaching, but in the course taken up by the majority of students who had a medical career in view. So far as elementary practical physiology was concerned, as distinct from biochemistry, reliance was still placed largely upon an experimental treatment of the rudimentary phenomena exhibited by amphibian muscle and nerve, and there seemed little doubt that a serious attempt to incorporate, even in elementary courses, experiments in human physiology would be amply justified in its results.

#### MENTAL DISSOCIATION

Dr WILLIAM BROWN, the President of the Section of Psychology, gave an address on mental unity and mental dissociation. Its substance may be stated as follows. Considered in its most general aspect, man's mind was a unity—one, and indivisible. So too with regard to its function, in the broadest sense mind had but one fundamental function—a purposeful striving toward a definite equilibrium, the calm of which was satisfaction. But, like all other things, mind had undergone development from the simple to the complex in its varied experience. It had employed partial activities to aid and favour the attainment of its one fundamental objective, and its structure had been moulded without being divided, to subserve these partial ends. Mind, therefore, although one, was not homogeneous, but exhibited structure, and presented itself as an association of partial activities developed by varied moulding of a single originally homogeneous substratum. As the mind could, by association, combine partial activities to its advantage, so also it could reject partial activities which, in changing circumstances, opposed its fundamental aim. This dissociation was a normal, not a pathological, process of the mind—a process, not of annihilation, for the mind could not obliterate the structural modification upon which the partial activity had depended but one of reduction to mere potentiality, and degradation from participation in the practical affairs of life. Since the structural modification remained, circumstances might revive the potential partial activity into actuality. It might be supposed that if a complex group of such potential activities was suddenly brought into play and if at the same time the corresponding normal, but contrasting, group was degraded, the individual would exhibit, not a division of the mind, but a new personality. Instances of alternating personality of this kind were well known and it was in such cases that the pathology of dissociation could be detected. It was not that dissociation was in itself an abnormal process—the contrary was the case—but that in these instances it was incomplete, a tendency which was repressed was, as it were, rejected and accepted at the same time—rejected by clear consciousness, but still clung to by the mind.

Dissociation is a normal process might, however, be abnormal in its incidence, just as the contraction of the uterus, although a useful function, might be inopportune if untimely. The dissociation, instead of suppressing an undesirable activity might affect a part of the normal mental processes and put out of action an essential element in the normal working of the mind. Cases of shell shock afforded examples of this, a forgetfulness of the events immediately succeeding the catastrophe indicating the loss of a partial mental activity. The unity of the mind was not destroyed, but its adaptation to the changing circumstances of existence was impaired. The physical phenomena associated with the shock, such as tremors, mutism and paralysis, which would pass away under the influence of an intact mind, were severed from their psychical counterpart—feared—and became fixed. While treating cases of shell shock in France, Dr Brown found that a large proportion showed a more or less extensive amnesia for events that had occurred immediately after the explosion. These patients were easily hypnotized, and under a light hypnosis the lost memory could easily be restored, and he found that if at the same time the terrifying emotion were also recalled, the accompanying physical symptoms disappeared spontaneously. This result he explained in terms of a theory of reassociation (*BRITISH MEDICAL JOURNAL*, June 14th, 1919) by re-associating the whole of the lost experience in all its emotional vividness the physical manifestations became linked up with their psychical counterpart, the mind became re-synthesized, and the physical symptoms, coming once more under the sway of the entire mind, could disappear.

#### LITERATURE OF THE VAS DEFERENS

In the Section of Zoology the committee (Dr F. A. F. Crew, Mr T. T. Cunningham and Professor J. S. Huxley) for the experimental investigation of the effects of vaso-

ligation, cryptorchidism, grafting etc., on the seminal tubules and interstitial tissue of the testes of animals, presented a further report. The right vas deferens was ligatured, in the rat, in two places and a piece between the ligatures cut out. The animal was killed 104 days after the operation. The end of the vas next to the operated testis was found to be closed and the spermatic blood vessel uninjured. Abundant active sperm were obtained from the epididymis of the non-operated testis, and the operated testis showed perfectly normal spermatogenesis. The epididymis of the operated side was distended with semen its diameter being twice the normal. Experiments on ligation of the vas efferentia were carried out on the rat. They showed that closure of the lumen of the vas efferentia caused complete disorganization of the seminal epithelium in six days. As the operation involved no interference with the circulation of blood in the testis, it was evident that the effect was to be attributed to increase of pressure within the tubules. It followed therefore that if the vas deferens only were ligatured the absence of injurious effect was due to the fact that the great space contained in the long coiled tube of the epididymis prevented the increase of pressure in the seminal tubules, the epididymis acted as a reservoir for the semen and became greatly distended in consequence.

The conclusion drawn was that when the distension and pressure increased to a certain point within the epididymis, absorption of semen was increased, an equilibrium was reached and no further rise of pressure occurred. In one experiment, in the rat, the membrane through which the vas efferentia pass was ligatured on the left side and the right testis was detached from the scrotum and fixed to the abdominal wall by a ligature passing through the guberniculum. The animal was killed after sixteen days when the right testis was found to be atrophied being only about half the normal size, and its seminal epithelium was completely disorganized. The left testis was functional and the ligature loose.

#### MENTAL STRESS AND THE PSYCHOLOGY OF ACCIDENTS

In a paper read to the Section of Physiology Dr P. J. S. McDONNELL, Professor of Physiology King's College, London, maintained that the general effect of mental stress was as related with increased sympathetic activity, there is an increased rate of the heart and vaso-motor tone which together bring about a great elevation of blood pressure. Further, there is definite evidence that alimentary activity in general is diminished as shown in the reduction in salivary and gastric secretion and the marked delay in the emptying of the stomach. Such conditions, says Professor McDONNELL, suggest a largely responsible factor in many alimentary ailments and in part also for undisturbed circulation. With regard to accident causation Mr I. Farmer in a paper read to the Section of Psychology said that it had been shown that the distribution of industrial accidents among individuals exposed to the same risk was not such as can be explained by chance. The typical curve of accident distribution exhibited special features which seemed to point to the conclusion that each person had a given degree of accident proneness which would determine to a large extent the number of accidents he would sustain in a given period of exposure. This conclusion was reached as the result of certain sensory motor tests of the rapidity and accuracy of visual, auditory, and tactual reactions.

#### FIRST RECORDED CASE OF COLORED BLINDNESS

In the same Section Dr Edridge GLEN claimed that the celebrated physicist Robert Boyle was the first to record a case of colored blindness. Two cases came under Boyle's notice concerning one of which, a girl of 18, he writes in 1653 that

"she can distinguish some Colours as Black and White but is not able to distinguish others especially Red and Green. And when I bled her a Drop or a few and gave her Pills with Tincture of Coloured Silk she looked as white upon it but told me that I could not seem Red but of another Colour which one would have been a Description to be Dark or Dirty one and the Tincture of Silk that were finely Coloured she took in her Hand and told

me they seemed to be a light colour but could not tell me which only she compared it to the Colour of the Salt in Stuff of the Thread of a Red that brought her to me and said that the Colours were very much alike. And when I asked her whether in the Evening when he went alone to walk in the Field which she much delighted to do the Meadows did not appear to her (as they did in Green) She told me they did not but seemed to be of an old Darkish colour and added that she had a mind to gather Violet the he had in that Place where they grew. I was not able to distinguish them by the Colour from the neighbouring Grass but only by the Shape or by feeling them.

Some years previously this girl had lost her sight, which gradually returned, with the exception of the colour sense.

#### AMOEBOID MOVEMENTS

Mr C. F. A. PRATT contributed to the Section of Zoology some observations on amoeboid movements. As these were, he said, independent of permanently differentiated contractile structure, the theory had been advanced that they were due to a lowering of the surface tension at one spot. Microscopical dissection and other evidence showed that this view is untenable and that the movement was associated with the ready changes of state of the protoplasm from a fluid "sol" to a contractile "gel" and vice versa. The changes were easily observed in the *Lamprocyba* type of amoeba, in which each particle of protoplasm underwent a more or less rhythmic change of state from sol to gel.

#### THE FERTILITY OF THE SEA

Mr H. W. HERVEY reported to the same Section some ingenious observations on the fertility of the sea. Its animal life was he pointed out ultimately dependent on minute plants which in their turn were dependent on the supply of phosphates and nitrates in the water. Such salts were in general abundant in the deep water of the open ocean but absent from the surface where also the presence of light rendered vegetable life possible. Where, however, currents brought the deep water to the surface, there minute organisms were abundant, giving the water a greenish hue contrasting with the deep blue of the barren areas of the ocean. Around our coasts the cooling of the surface in winter caused mixing with the warmer layers below and plant life being carried at that season the organisms from the deep of decomposing accumulated. In spring a rich outburst of diatoms utilized the salts, while in life's summer a second outburst of plant life occurred utilizing the salts recruited from the corpses of the spring and early summer growth.

#### HEAD HUNTING

In the Section of Anthropology many several papers of interest were read by Dr J. P. HUTTON on the savage custom of head hunting. A recent authoritative work on Borneo traces the custom to a desire for human beings as an ornament or for human beings to accompany the dead in the next world. Dr Hutton satisfied himself that in Asum it had a different significance for it appeared to be connected with a belief in the fertilizing powers of the dead—for the soil for stock and for the human population. To assist these fertilizing powers, phallic stones were erected as symbolic altars, places for the soul and similar stones were intimately connected with head hunting.

#### EDUCATION OF UNCIVILIZED PEOPLES

In the Educational Section Mr Rivers SMITH made some interesting observations on the educational policy which appears to have been officially adopted for tropical Africa. The best persons he considered, were to be looked for by the adaptation to the demands of civilized societies of what can be retained of native social systems, and by endeavoring to promote the growth of the new order through a natural process of evolution rather than by an undue insistence on Western systems. Care he urged, should be exercised not to distort a good African by the inoculation of ideas and tastes which could not find expression in an African community. The aim should be to produce a new but firm conception of the African rather than a spurious imitation of the European.

SATURDAY, SEPTEMBER 10TH, 1927

## DARWINISM AND THE ASCENT OF MAN

THE President of the British Association for the Advancement of Science stands in the position of an ambassador called to speak for Science in the Court of the World, and this year at Leeds the honourable responsibility has fallen to Sir Arthur Keith. He has interpreted his duty in a characteristic way by saying, on behalf of the whole body of scientific workers, that the future of thought is being built on the foundations that Darwin so securely laid. In this connexion it is interesting to look into the work of the thirteen sections of the British Association, and no one who does this seriously can fail to realize that Darwin's mind has fundamentally affected the main lines of work of nine or ten. Sir Arthur Keith refers to Darwin's wise generalship in giving twenty-two years, at least, to preparing to launch his main contribution to science, we now know that those years were not spent in hatching the idea, we have in printed form the preliminary sketch written as Darwin began to ponder over his masterpiece. But Darwin was not only a master artist who saw into Nature as few others have done, he was also humble and patient enough to collect details and check them, and to adjust his ideas to new light from fresh facts. Sir Arthur Keith did not concern himself with the details of the picture of evolution as painted by Darwin or as elaborated by constructive criticisms and, at times, obscured by verbal subtleties since his day. Darwin's main plea for the survival of some and the elimination of other variations in the struggle for the life of the individual and the group is still held to be of great importance and we are beginning to perceive somewhat dimly how all sorts of reactions between organism and environment are influences for change.

The advance in our knowledge of the process of evolution since Darwin's day has not been so marked as might have been hoped, there have been too few who could even aspire to bend the bow of Ulysses. The trend of thought has rather been in the direction of following out the idea of evolution in the phenomena of growth and health and disease, in the study of social organizations the world over, in theory and practice of education, ancient and modern in economics and psychology, in poetry, and deep down into the innermost recesses of philosophy and religion. The great influence is still unfolding its power, and it is well that Sir Arthur Keith should stand forth in his high position to make a simple statement, to tell the plain truth—that there is no part of the study of life and thought that can be built up for the future, save on the basis which was crystallized out from the work of hundreds of researchers by the synthetic imagination of Darwin and Wallace, and their humble patience in collecting a unique store of artillery for the controversy ere it was launched.

It has been natural for vested interests in the field of thought and for some indolent persons to listen to details of criticism of Darwin's work, which has necessarily been modified especially by advances of physiological research, and some of them have thought

that the idea of evolution was fading, that the clear view had gone. Sir Arthur Keith has the support of all scientific workers in proclaiming that the idea of evolution is as yet young, and that some cherished opinions may need deep modification, however much casuistic subtleties may delay and prolong crises and turn men's thoughts from the essentials. Some of Darwin's friends and successors in their controversial agitation had little peace of mind in which to build up for themselves a picture in proper perspective, we need rather to leave controversy alone now our representative has repeated the fundamental message. If we are wise enough to do this, we may hope to work towards an enrichment of the picture of the evolutionary processes that some bellicose politicians have so misapprehended.

The idea of evolution is treated by Sir Arthur Keith in its connexion with man, and his modesty has prevented him from enlarging upon several points which would have brought in his own work and his own views. He thinks that our pithecoïd ancestor inhabited the tropical or subtropical forests of Miocene times, and emphasizes the value of the work of Pilgrim and of Gregory on the apes of that time, of whom, unfortunately, only teeth and jaw fragments have been found. Since that distant epoch we and our anthropoid ape-relatives have diverged, one towards the warm forests the other apparently towards more temperate lands. But the divergence has not gone so far as to obscure relationship, and Sir Arthur Keith pays his tribute to the work of Professor G. H. Nuttall on the similarity of blood reactions between apes and ourselves, and of Professor Elliot Smith on the human brain. The difference even in the latter is only a difference in proportions, the human brain contains no formation that is not in the ape's brain. The President, however, from his long studies of ancient skulls, sees clearly that we have not an orderly file of stages from ape to man, some skeletons are very man-like in certain features and very ape-like in others, and he illustrated this difficulty most aptly by a reference to the recent, but fortunately closed, controversy as to whether the—on the whole—very human skull and the very ape-like jaw at Pliocene could belong to the same type. It is now practically universally agreed that they did.

To unravel man's pedigree we have, Sir Arthur Keith said, to thread our way not along an orderly line but through the meshes of a complicated network. By this he means that the ancient skeletons which we know are all to some extent departures from the main human stem in some feature or another, and we have to infer from one and another what the common ancestor was like. We could have wished that, from the President's long studies of growth, it had been deemed appropriate to include in the address some illustrations of the concept that differences in growth make adults aberrant, and that it is not necessary to suppose that any adult ever showed just the whole assemblage of characters which we conceive of as ancestral. The young are more akin to one another, and Sir Arthur Keith rightly pressed home the idea that the study of experimental embryology is one of the great hopes of the future. So far as man is concerned, embryological observation—extended well into the period of post natal growth and bringing in all that can be gathered about the influence of thyroid, pituitary, and other endocrine secretions on the basis of Sir Edward Sharpey-Schafer's great work—is likely to be of immense importance for the advancement of knowledge. Since man has come into existence

the levels of land have changed, climatic zones have moved, deserts have spread, and with all these changes have gone alterations in growth that need to be worked out in far greater detail than has hitherto been possible. When more has been done in the way of the combined study of man and his environment we shall see better how it comes about that the adults of related stocks differ from one another so much more than do their young, we shall have an idea of the influence of growth changes in promoting evolution of types, and we may even glimpse some understanding of the mystery of the transmission of new characters of growth to the germs of future generations.

We may interpret Sir Arthur Keith's message to the world as a clear statement that the positions won by Darwin are definitively held, and that the field is clear for a great advance in the understanding of the evolution of man by synthetic work, gathering in the facts that geographers, anatomists and physiologists, sociologists and psychologists place at the disposal of the Science of Man.

### RESTORING THE DISABLED

The end of the great war left every combatant nation with a number of damaged individuals on its hands, for whose cure and relief it felt itself responsible. Certain nations realized in addition that the average standard of health of their members as shown by the examination of recruits, was much too low. Never before had the entire young adult manhood of the English speaking nations come under thorough and skilled inspection. The result in this country gave a severe shock to our complacency, and 'Are we a CS nation?' became a familiar question in our newspapers. But we have had so many other troubles in the last eight years that perhaps our attention has wandered a little from the question of the improvement of the physical fitness of our people. In the United States however the question of rehabilitation, as it is called, has not been allowed to slide into the background of domestic politics but has been earnestly discussed by a number of social workers and medical men. The United States has only so comparatively recently changed from a nation preponderantly agricultural and pastoral in its occupations to one that is increasingly urban and industrial that it was natural for the average American to assume that the physical development of his fellow citizens was as good as that of the embattled farmers of Emerson's poem and the days of Washington. It was to him collectively a great surprise to find that the enforcement of the draft showed how many townsmen were physically unfit and he is not disposed to accept this depressing report without making strong efforts to improve matters.

As this unfitness was generally the result of the maladies and unwholesome conditions of childhood and youth as well as of adult life the adequate treatment of acute and chronic disease in all its stages assumed a position of great importance, and rehabilitation has come to connote the making good of the organism damaged by the diseases of peace as well as by the effects of warfare. Among the States which have seriously gone into the matter that of New York is conspicuous and the New York Academy of Medicine has taken the lead in investigating the facts of the situation as regards the care and management of convalescent homes. One outcome of these inquiries takes the form of a report of the Public Health Committee, which consists largely of epitomes or reports

by subcommittees on the convalescence of surgical, medical, neurological and pediatric cases respectively. The authors of these elaborate reports, among whom is Dr Frederic Brush, the medical director of the Burke Foundation at White Plains, New York, seem to have considered all aspects of the question, including provision for the treatment of cases which are not strictly convalescent but chronic, and also those cases of poor health which by treatment in a country institution may be saved from the breakdown which seems imminent and might otherwise be inevitable. Dr Brush uses the name of 'preventoria' for proposed institutions intended for the care of such patients, and he states that over 30 per cent of the 6 000 patients treated yearly at the Burke Foundation are in the 'preventive' class. The need of continuity of treatment and the establishment of liaison between the general hospital and the convalescent home is insisted upon for it appears that in the United States it is not usual as it is in London for the hospitals to maintain their own convalescent institutions. About 300 000 to 400 000 patients were cared for last year in the United States in convalescent homes, and of these cases if the experience at White Plains may be taken as typical some 25 per cent would be more properly called chronic than convalescent. Dr Brush expresses some of the most important of his conclusions in these words: 'Every community of upwards of 200 000 people should have one large general convalescent hospital serving the community open to all, receptive to the man that walks in off the street to the private doctor, and the employer—not alone to the hospitals and health organizations. It is not that the large places can be run at less cost per day—a prevalent fallacy. It is because of the superior convalescent therapy that is inherent in the larger grouping. Also special convalescent homes are needed. They may be small and established for heart disease first the neurological borderlines rheumatism, special dieting etc.'

We have not yet in this country inquired into the needs and origins, or formulated our requirements with such thoroughness as has been done in New York, but we may hope that as far as convalescents are concerned we have provided and shall continue to provide for them adequately. The organizers of our charitable efforts might well consider the plea put forward in America for a widening of the field of institutional treatment. In all or nearly all of the States throughout the Union, organizations have sprung up whose object is to restore the disabled worker to health, or at least to a condition or wage earning capacity. At the beginning of this year a monthly journal called *The Rehabilitation Review* was established under the editorship in chief of Dr Fred H. Allbee whose work in the treatment or discharge of bones and joints is well known and having for managing editor Mr Frederic G. J. Iton. The advisory editorial staff of nearly ninety on which Canada and nearly every state of the Union are represented includes also nine names of European surgeons and physicians widely known in connection with medical as well as surgical rehabilitation. If such a publication succeeds, as it should in enlisting the sympathies and interests of workers in rehabilitation generally, it

<sup>2</sup> The Essentials for Convalescent and Sub-standard Health Care. By Frederic Brush M.D. Medical Director, The Burke Foundation for Convalescent White Plains New York. Reprinted from Hospital Social Service, Vol. 1, 1927, 36.

<sup>3</sup> *The Rehabilitation Review*. Devoted to the Persuasion and Employment of the Disabled. Representing the National Organizations Interested in the Welfare of the Disabled. 20 East 23rd Street New York.

should become a most valuable and beneficent power, not only in America, but in all the civilized world, but there seems some risk of its straying from its proper field of action and trenching on the domains of active surgery or medicine. In the three numbers that have reached us there are articles describing in detail surgical operations for the relief of the disabilities produced by polyomyelitis, and on the treatment of fractures, which excellent in themselves, would be more appropriately published in the pages of a special or general medical or surgical journal. We offer in all friendliness the suggestion that similar contributions should not in future be admitted, lest their presence should alienate the interest of the many non-medical workers in rehabilitation.

#### HEALTH OF BRITISH TROOPS IN CHINA

Our latest reports from China show that the health of the troops continues very satisfactory in spite of the difficulties attendant on the confinement of a large body of troops within a small space in a town like Shinghai. Dysentery has been almost entirely absent, and no case of cholera has occurred among the troops. There have been a number of cases of malaria, but the majority of these were relapsed cases contracted in India. Cases of pneumonia have continued to occur through the summer months. There has been a small outbreak of enteric fever among the men of the 1st Battalion Middlesex Regiment at Wei-hai-wei. The first case occurred on July 14th, and by July 29th fifteen cases had been admitted to hospital, but no further cases have since been notified. The source of infection is uncertain. Venereal disease has been a difficult problem from the time of arrival of the troops in the Far East, but the incidence appears to be declining. Ample hospital accommodation exists both in North and South China, and a convalescent depot of 400 beds has been established at Wei-hai-wei for troops from Shinghai and Hong-Kong during the hot weather. The local medical and public health authorities have rendered much valuable assistance. The Canadian Department of Soldiers' Civil Re-establishment has very kindly provided accommodation in its hospital at Vancouver, B.C., and patients requiring long convalescence or subsequent evacuation to England are being sent there. The journey home through the monsoon during the hot weather is thus avoided.

#### CHARLES DARWIN'S HOUSE

In our article this week (p. 459) on the annual meeting of the British Association at Leeds brief reference is made to the announcement by the President, Sir Arthur Keith, regarding the proposal to purchase for the nation the home and surroundings in Kent where Charles Darwin lived for forty years. The appeal for funds with which to acquire this historic house has now resulted in a munificent offer from a member of our profession, Mr. George Buxton Browne, F.R.C.S., of Wimpole Street, London, who retired from practice some years ago. Downe House (or Down, as it used to be spelt) stands in a retired corner, about sixteen miles from London, between the high roads to Westerham and Sevenoaks. In 1842, when Darwin bought it and made it his home for life, a long coach drive was the only means of access. Of these quiet surroundings, in which so much of his epoch-making work was done, Darwin wrote: "My life goes on like clockwork, and I am fixed on the spot where I shall end it." He made a number of additions and alterations to the house and grounds, and died there on April 19th, 1882. Mr. Buxton Browne's motive in offering to make himself wholly

responsible for having the estate and establishing a fund for its upkeep is to permit future generations to visit Darwin's home. The General Committee of the British Association on September 6th authorized its President to accept with gratitude this offer. It is understood that the donor has expressed a wish that Downe House, with and without, should be restored, so far as is now possible, to its condition in 1882, and that some appropriate medical man of slender means should be appointed resident custodian. All Darwin's preliminary study for *The Origin of Species*, as well as the writing of that book and *The Descent of Man*, took place at Downe. It is intimately associated, therefore, with the greatest works of the great naturalist.

#### NEW INSURANCE DRUG FUND REGULATIONS

DRAFT regulations amending the National Health Insurance Medical Benefit Regulations in so far as payments to pharmacists are concerned have now been issued by the Minister of Health. They are in accord with the proposals set out in a recent circular, on which we commented in a leading article in the *JOURNAL* of August 20th last (p. 315). In that article we noted a curious proposal whereby Insurance Committees might if so advised, reserve up to one-tenth of their Chemists' Fund for special distribution to those chemists who had been continuously for specified periods of time on the lists of those supplying drugs and appliances to insured persons. The draft regulations now provide that where a portion of the fund is so appropriated the Committee "shall increase the sums payable to those persons in respect of the ven to which the Chemists' Fund relates in proportion to the accounts submitted by them and passed by the Committee in respect of that ven." So far no explanation has been given of the purpose of this novel provision, nor of the circumstances in which it may be expected to be put into effect. It will be interesting to ascertain or to observe these, inasmuch as it is conceivable that corresponding conditions might be held to arise in connexion with the Practitioners' Fund. A further draft regulation directs the Insurance Committees to furnish returns of the "capitation fees and other sum paid by them to insurance practitioners in respect of the supply of drugs and appliances to insured persons." This is with a view to the Minister ascertaining the yearly balance left in the Medical Benefit Fund after these and the other necessary payments have been made, the whole of which balance has, under the new conditions, to be handed over to the chemists. One important point must at once be raised with regard to this on behalf of dispensing practitioners. It will be remembered that prior to the present calendar year, the dispensing capitation fee for practitioners was 2s. The Insurance Acts Committee put forward a claim, which it considered fully justified for 2s. 6d. The Ministry, in a letter dated October 9th, 1926 offered an increase to 2s. 3d. as from January 1st, 1927, and the Conference of Representatives of Local Medical and Panel Committees, with some reluctance, resolved "That the offer of 2s. 3d. be accepted as the best under the circumstances." The new regulations bring about a radical alteration in the circumstances, and this will clearly justify the Insurance Acts Committee on the annual conference next month in reopening this question if on the merits of the case, they consider it desirable to do so. It will be the more necessary to consider this if any proposal be made—as it may be—to agree that no further alteration of the Medical Benefit Regulations shall be made for a definite period of time. Because dispensing practitioners decided to forego their full claim on whatever balance there might be in the fund under the then conditions it does not follow that they would be willing to forego it if the effect is merely to add to the sum distributable among the chemists. It would be

interesting to know what one penny on the dispensing, expiation fee of practitioners represents per insured person on the sum distributable to pharmacists

### TELEGRAPHISTS' CRAMP

Telegraphists' cramp forms the subject of a report by Miss May Smith, Dr William Culpin, and Mr Eric Farmer to the Industrial Fatigue Research Board. Though it does not appear to record any notable advance in the prevention of this disorder it is possible that the tests devised by the investigators may be of use in any further work which aims at assisting vocational selection amongst would-be entrants to the telegraph services. This is the view taken by Professor Greenwood in a statistical note appended to the report. The observers found that telegraphic work makes more exacting demands than allied occupations, and that these demands affect the emotional rather than the intellectual life. Consequently a majority of the "cramp" subjects examined had psychoneurotic symptoms, commonly allied to muscular weakness. Though in many cases muscular tests did not differentiate the subjects from normal people, tests applied to young learners of the age of 16 showed that it was possible to distinguish those with psychoneurotic symptoms from those of more stable development, but only 100 learners were examined. Six of these had sufficiently acute symptoms to admit of classification in recognized groups of psychoneurosis. Eleven others approximated to the type of the majority of sufferers from cramp, and were afflicted with psychoneurotic symptoms and weak muscular co-ordination. Fifty-four showed no such predisposition, and twenty-seven were slightly unstable. The report seems to suggest that the 20 per cent who had psychoneurotic symptoms would have nervous breakdowns in some other occupations also, but would be very liable to "cramp" in telegraphy. At the same time they might be efficient at some other occupation where their emotional make-up did not receive constant stimulation in the work. The investigations indicate perhaps that little can be done at the moment except to leave the selection of entrants to the telegraphic service to those who are at present responsible. Doubtless these authorities succeed in eliminating at all events a portion of the 20 per cent of psychoneurotics, whereas the method of selection reached by Dr Culpin and Mr Smith would exclude such a proportion of post-office workers as to lead Prof or Greenwood to describe it as very drastic. It is interesting to note that in America, where telegraphy is not a permanent occupation, telegraphists' cramp is hardly recognized as a disease.

### THE BIBLIOGRAPHY OF CANCER

For some years past the French anticancer league has published, as a supplement to its bulletin, a number of abstracts of papers on cancer from current literature. It now proposes to institute a more complete analysis in the form of a quarterly fasciculus, under the title of *Index Analytique Cancerologique*. It is intended as announced in the first fasciculus to give a classified list of the titles of all papers relating to cancerous disease which appear in the periodicals and publications of the entire world, together with a summary of the contents of such as appear to call for special notice. It is calculated that the annual volume will comprise about 600 pages containing some 2,500 references. The present fasciculus contains nearly 600 references, and there are one or two summaries on every page. Where authors have given summaries in their papers these are to be reproduced word for word in the abstracts. The underlining is naturally one of great magnitude and can only be brought to completion gradually, but the hope is expressed that

it will have an international character. With regard to organization, it is proposed to establish an international committee to collect material from the respective countries. The members of the French committee, already constituted, are Borel de Nabel, Hattis and Regaud, and Roussy, with Fauchon as general secretary, and similar committees have been appointed for Germany, Belgium, Denmark, Spain, Holland, Norway, Sweden and the U.S.S.R., it is hoped that other nations will join the scheme. The material collected by the national committees will be transmitted to the French editorial committee, and the whole will serve without other alteration than the translation of the titles and abstracts, for editions in different languages. A so-called similar project has already been undertaken in this country and is the direction of the Council of the British Empire Cancer Campaign. A strong committee was formed, of which the late Sir William Lushman was chairman, and a review started with the title of *The Cancer Periodic*, the first number of which appeared last year. The deal intended was to give an abstract of every important publication bearing upon the problems of cancer research. Thus the scope is more limited than that of the French project, and no attempt is made to include the titles of every paper published on the subject. Fifteen numbers of the review have now been issued, and it cannot fail to be considered excellent in every respect. As is well known the term "abstract" is very elastic, sometimes it refers merely to a brief statement of what a paper is about, and may give little more information than the title, at other times it aims at giving a concise account of the contents of the paper, and in its best and most useful form serves almost as a substitute for the original article. *The Cancer Periodic* appears to favour the latter type of abstract: it requires skill and a considerable amount of space but there is an evident intention to be unflinching in both. Of the necessity in these days for good works of this kind there is no need to speak.

### INCOME TAX THE THREE YEARS AVERAGE

SECTION 29 of the Finance Act, 1926 which comes into operation for the first time this year substitutes the basis of the previous year for that of the previous three years. In so doing it fulfils one of the recommendations of the Royal Commission on the Income Tax and incorporates a modification suggested by that Commission with a view to the avoidance of hardship. If the option is to be exercised the election to adopt the three years' average must be notified to the local officials—in practice to the inspector of taxes—not later than October 5th 1927: this date is to be carefully noted. It will be opportune therefore to give a brief account of the conditions and limitations of the option. The assumption underlying the provision is that where profits have increased more or less steadily no hardship is involved in the change of basis, but where in consequence of the change, the profits of unusually bad years are excluded from the calculation, then some special concession is due, because those poor years have not yet had an adequate effect on the taxpayer's liability. An example may make this point clearer. Suppose that a practitioner who ordinarily earned £1,200 a year for some reason earned only £600 in 1925 then up to and including the financial year 1925-26 he will have paid tax on an assessment of £1,200, and for 1926-27 on 1/3 of (£1,200 + £1,200 + £600 =) £3,000—that is, on £1,000, and if he is assessed for subsequent years on his earnings for the previous year he is left in the position of having paid on £400 more than he has earned. The statute therefore provides what may be called a test of hardship, and the test laid down is whether or not the amount of the average profits for the six years 1918 to 1923, inclusive,

exceeds either of the profits for 1924 or 1925, if it does, then the person or firm to be assessed can elect to adopt the three years' average for 1927-28 and 1928-29. It should be borne in mind that the election applies to both years and not to either separately. The exercise of the option calls for some judgement, because so far as 1928-29 is concerned the balance of advantage turns to some extent on the amount of the profits for 1927, which, of course, are not now ascertainable—though they may be capable of a reasonable estimate—unless the end of the practice year precedes October 5th, whereas, in fact, it is usually December 31st. It will frequently happen that the individual or group of individuals owning a particular practice in 1927-28 will not be identical with those owning the same practice throughout the six years 1918 to 1923. The point is dealt with in the statute, but cannot be fully explained in a brief note. In effect, if at least one individual has been the owner or a part-owner throughout the whole period, then the comparison is made as if there had been complete identity, on the other hand, if there has been a complete change in ownership, then the periods in which none of the existing owners were proprietors of that practice have to be excluded from the years 1918 to 1923, and an average taken of the earnings of the remainder of those years.

#### THE NATIONAL INSTITUTE FOR THE BLIND

The report of the National Institute for the Blind for the year 1926-27 gives an account of the work of the largest institution for the blind in the world. It is becoming more and more the co-ordinating agency of the numerous small local blind aid societies throughout the country, it is through it that for many purposes various statutory authorities assist the blind, it helps the blind in relief and training, in finding employment, and in organizing the marketing of their handwork. For these reasons alone it would be worthy of all sympathy and assistance. But these aspects of its work are not the greatest features of its activities. Perhaps that which is the most helpful is its action as the greatest publishing agency for the blind. Embossed books in Braille and Moon types are prepared and printed by the Institute for the whole Empire. During the year under review nearly 400,000 publications were issued, and ten periodicals—including two newspapers, a literary review, a popular monthly, and monthlies devoted to juvenile literature, music, massage, and religious subjects. The latest innovation is the *Braille Radio Times*, of which 1,500 copies are now sold weekly. Wireless broadcasting has been an inestimable boon to the blind, and the new journal gives them information about the programmes and as to how to keep their instruments in order. The books published for the blind include classical as well as modern works, and the students' library which is mentioned has been described as "a library of books unobtainable from other libraries." Nearly 800 new volumes for students have been prepared by hand by volunteer Braille writers during the year, and the total of books now in this library is 5,000, valued at £11,000. A new machine is being designed whereby it will be possible to reproduce from an original Braille manuscript a number of copies. It is a marvel of ingenuity, the paper sheets from the writer, when inserted in the machine, act as selectors, allowing small plungers to rise by means of compressed air. There are now 4,000 of these plungers, so the delicacy of the apparatus may be imagined. The work of the Institute in the foundation and maintenance of homes for blind babies, "Sunshine Houses," is too well known to require more than mention. But greater than this is its work at Chorley Wood College for Girls with Little or No Sight, it is a fine piece of work, and we are pleased to note that the College has been

recognized by the Board of Education. The work of the Institute is controlled by an executive committee. The names of its members are given, with a "Who's Who." We note that Dr. Brackenbury, the Chairman of Council of the British Medical Association, is now a member representing the Association of Education Committees, Mr. Bishop Harman is the advisory ophthalmic surgeon to the Institute. The report contains a clear financial statement of the Institute and its subsidiary departments, prepared as prescribed by the Ministry of Health and the Board of Education. Last year, owing to the general depression caused by the severe industrial crisis, there was a decline in funds of £15,000. How can the Institute be helped? The answer is given in the report. Perhaps the most valuable form of assistance is the annual subscription. The total amount of annual subscriptions received should be the basis of the funds upon which the Institute can calculate in respect of maintenance and extension of activities. The head office is at 224, Great Portland Street, London, W.1.

#### MEMORIAL TO THE LATE DR J. G. ADAMI

In view of the personal popularity and scientific eminence of the late Dr. J. G. Adami, F.R.S., it is fitting that a memorial should be established in the University of Liverpool, to which, as Vice-Chancellor, he devoted himself with such energy and enthusiasm in his later years. It has been suggested that the most appropriate form for a memorial to take would be the creation of an Adami Fellowship in Pathology, for this the sum of £3,000 would be required. There must be very many old students, friends, and admirers, both in Montreal and Great Britain, who would wish to associate themselves with this tribute, and their co-operation is earnestly invited. An alternative and less ambitious proposal is the endowment of an Adami Library of Pathology in connexion with the Medical Library. Donations to the Adami Memorial Fund may be sent either to the Treasurer or Registrar of the University of Liverpool, or to Heywood's Branch of the Bank of Liverpool and Martins, Limited.

#### NEW REGULATION FOR EDINBURGH M.D. DEGREE (Correction)

In our last issue—the annual Educational Number of the *BRITISH MEDICAL JOURNAL*—we printed at page 427 a paragraph on the new regulation for the examination for the M.D. degree of the University of Edinburgh. This repeated almost word for word the information already given in our issue of April 2nd, 1927 (p. 639). We regret to learn that its appearance in the Educational Number under the general heading "Degrees for Practitioners" has caused misapprehension among practitioners who are not Edinburgh graduates. We are officially informed that the new regulation referred to is simply a change in the nature of the clinical examination for the degree. The M.D. Ed. degree is, now as hitherto, conferred only on graduates of the University of Edinburgh. We hasten to correct the wrong impression thus inadvertently conveyed.

#### THE MEDICAL REGISTER UNTRACEABLE PRACTITIONERS

We publish in the *SUPPLEMENT* this week (p. 126), at the request of the Registrar of the General Medical Council, a list of the names of those medical practitioners who have not replied to his inquiries as to the accuracy of their postal addresses. Any practitioner who finds his or her name included in this list should communicate at once with the Registrar of the General Medical Council, 44, Hallam Street, Portland Place, London, W.1.

## Ireland.

### MEDICAL COUNCIL (FRET STAFF)

The result of the voting for the election of two direct representatives of the medical profession to the Free State Medical Registration Council established under the Medical Practitioners Act, 1927, was as follows: Dr Maurice Hayes, 1,141 votes, Dr R J Rowlette, 926, Dr P E Hayden, 552. Dr Hayes and Dr Rowlette were declared elected.

### ROYAL MEDICAL BENEVOLENT FUND SOCIETY

At meetings of the Central Committee of the Royal Medical Benevolent Fund Society of Ireland, held in the Royal College of Surgeons, Dublin, during July and August, the following grants were made:

Medical man aged 33 in hospital suffering from pulmonary tuberculosis £30 special grant  
Applicant aged 40 in reduced circumstances £15 special grant  
Applicant aged 75 income £26 per annum from curacies and old age pension £20  
Medical man aged 65 incapacitated through blindness income 10s. a week £50 special grant  
Widow aged 50 nine children six dependent income about £200 per annum £30 special grant  
Widow aged 57 health broken took in lodgers while she was able £30 special grant  
Widow aged 70 income from old age pension and £26 gift from friend £20  
Widow aged 35 left suddenly destitute through accidental death of husband four children under 8 years of age £50 special grant.  
One application was refused.

### FERMANAGH COUNTY HOSPITAL

The report of the Fermanagh County Hospital for the last year is, when all branches of its work be considered of a more encouraging nature than previous ones. The medical side is decidedly satisfactory, and the hospital is self-supporting to the extent of 44 per cent of its expenditure the County Council providing the other 56 per cent. The total income was £5,540 13s 3d. It is to be regretted that the committee had to close one ward of eight beds for want of funds. There is perhaps in consequence, a small waiting list for admission on the male side, and it became necessary to refuse some cases, such as tuberculosis of the spine, which might occupy beds for many months. There is a sum of £675 due still to the hospital by the County Council and if this were paid the governing committee could provide a x-ray apparatus, which is badly needed, and for which the electric wiring connexion has already been provided. The total income from dividends (bequests and gifts) is £148 13s 10d yearly the late Mr C Wilson, registrar of the hospital, contributed the sum of £1,027 10s. 8d. There was a considerable increase in donations, but this excellent institution requires all the help it can receive to maintain it in a state of efficiency.

## Scotland.

### PRESERVATIVES IN FOOD

The Scottish Board of Health has issued a memorandum dealing with preservatives in certain articles of food as amended by the regulations of December, 1926 and July 1927. The memorandum directs local authorities and officers of Customs and Excise to enforce the regulations and authorizes them to enter premises where articles to which the regulations apply are prepared, packed, labelled or sorted, with the object of taking samples for which they are authorized to make reasonable payment. It is forbidden to add any form of preservative to meat except that sausages and mince are allowed to contain not more than 450 parts per million of sulphur dioxide. Sulphur dioxide (including sulphites) may also be added to fruit pulp, dried fruit, jam, sugar, beer, cider and wines, and benzoic acid is permissible in unfermented wine, ginger-beer, pickles, and sauce. Among the colouring matters prohibited are compounds of antimony, arsenic, cadmium, chromium, copper, mercury, lead, and zinc, also gamboge

and picric acid. When articles of food contain preservatives these must bear a label of prescribed form stating that preservative is present.

### SCOTTISH ASSUMES PATHOLOGICAL SERVICE

The thirtieth annual report of the Board of the Scottish Assumptions for the year 1926 gives an account by Dr Reynolds the pathologist of the work done during the year. The laboratory is now accommodated in the university buildings, where facilities for the work are provided at the expense of Edinburgh University. The expenses of the research and reporting are provided by subscriptions from twenty-one institutions, and amounted to a revenue of £1,657 in 1926. A research has been undertaken into "The paths of infection to the brain meninges and venous blood sinuses from neighbouring peripheral foci of inflammation." Research in regard to neuroglia was also commenced, various lectures to students and graduates had also been given by the pathologist. As regards routine reporting work, 127 reports had been sent out to various asylums dealing with bacteriology, Wassermann's reaction, chemical examination of the cerebro-spinal fluid, and histology. The expenditure had been £1,037.

### MONTROSE ROYAL ASYLUM

The annual report of the Royal Asylum of Montrose for the year ending May 15th, 1927, shows that the number of cases under treatment during the year was 861, the number discharged being 64. Of these, 46 left the institution as recovered, 6 as relieved, and 12 as not improved while the number of deaths was 74. The daily average number resident was 746, of whom 720 were certified and 26 voluntary patients. The average age on admission was 49 years, an increase of almost four years on the average of the past five years. Seven cases were under 20 years of age and 25 or 17 per cent, were over 70. 5 of them being over 85 years of age. Forty cases had suffered from at least one previous attack. With regard to causes assigned for the mental breakdown, hereditary predisposition was ascertained in almost one-third of the admissions. Over 70 per cent suffered from general weakness, malnutrition, or active physical disease. As the patient gained in strength a corresponding mental improvement was found. Fourteen patients suffered from congenital defect, of whom 4 were also epileptic. Four cases were general paralytics, but it is noted that the incidence of this disease has greatly diminished during recent years. Fifteen cases were recorded of mania, 30 of melancholia, and 4 of alternating insanity. The number of patients discharged was 74 of whom 46, including 19 men and 27 women, had recovered. The recovery rate, calculated on a number of admissions, was 32.6 per cent. The death rate, calculated on the average number of residents, was 10.2 per cent, the average age at death being 60.4 years. With regard to voluntary patients, 26, or 39 per cent of the total private admissions, came under this heading. Of these 11 were discharged recovered making a recovery rate of 42.3, which compared favourably with the 32.6 per cent in the certified cases.

## England and Wales.

### HOME AMBULANCE SERVICE

At the end of June the Home Service Ambulance Committee of the Order of St John and the British Red Cross Society had 319 ambulances and 54 affiliated stations, four new ambulance stations were equipped during the June quarter. The number of patients carried during that quarter was 21,154 in the home service ambulances, and 7,572 in the affiliated ambulances. Altogether since its establishment the number of cases carried exceeds half a million. The liaison officer, Major Paget, in the course of a recent tour, visited many ambulance stations, and reported that there was evidence of an increased desire to make the service of invalid transport as nearly perfect as possible. At station after station he found proof of the generous spirit in which members of the Order and of the

Society spent themselves in the service of the sick and injured. He noted with particular satisfaction the care taken to keep the inside of the ambulances in good order, to provide clean and well used blankets and pillows, and to make arrangements for first-aid appliances, hot-water bottles, and other necessities. An ambulance, of course, does not last for ever, and in increasing number of stations are setting themselves to get the best type possible when the time comes for replacement. Special attention is directed to a new ambulance recently taken into use at Aylesbury, every detail, from the stretcher carriers to the door hinges, has been carefully considered by the officer in charge, Superintendent P. Marshall. The Home Service Ambulance Committee is taking in active part in the organization of the road service scheme for bringing first aid to the victims of traffic accidents. The lines on which this work is developing vary, according to local stations, from a full service, including roadside tents equipped for first-aid treatment, with an ambulance at hand and patrols on the road, to simpler but useful arrangements by which stretchers or first-aid appliances can be readily obtained at convenient points.

#### MANCHESTER POST-GRADUATE COURSE

The customary post-graduate lectures given at the Manchester Royal Infirmary will begin on Tuesday, September 27th. They take place on Tuesday and Friday afternoons, commencing at 4.15, and provide an opportunity for practitioners in the district to obtain information about recent advances in medicine and surgery. These lectures have been given regularly since the war, and the attendance is satisfactory, though it is thought that more practitioners in the immediate neighbourhood might take advantage of them, for they offer very valuable facilities. The Tuesday lectures are delivered by the active honorary staff of the hospital, the Friday lectures are largely given by other members of the Infirmary and University staff. Dr. J. Gray Clegg will speak on the field of vision and on the microscopy of the living eye, Dr. I. M. Brockbank on Dr. Peirce and Dr. Peirce in their relation to public health problems in Lancashire, Dr. Veitch Clark, the medical officer of health of Manchester, on immunization against diphtheria and scarlet fever and Dr. A. D. Macdonald, of the physiological staff of the University, on the causation of shock.

The Lloyd Roberts Lecture in Manchester will be given this year by Dr. Hector Charles Cameron at St Mary's Hospital, Whitworth Street, on November 1st. His subject is "The child in general practice, a study both of temperament and disease."

#### THE PUBLIC AND CANCER

It is a common practice nowadays to furnish the public with information on the subject of cancer, although there is, unfortunately, little to be gained at present from the knowledge imparted except emphasis on the importance of earlier or more frequent visits to the doctor. Dr. A. G. Anderson (M.O.H., Rochdale) has provided his council with a rather more complete summary than usual of our knowledge, or lack of knowledge, of this disease. The passages from his report for 1926 have been published as a pamphlet. After discussing the etiology of cancer, and mentioning the indications research affords of the possibilities of prevention, Dr. Anderson summarizes facts under this head which he thinks the public ought to know. After stating that the incidence of cancer is rising rapidly, and that during the last fifteen years the mortality has been increasing more rapidly amongst men than women, he goes on to urge that diagnosis and treatment must not be delayed, that an attitude of fear, despair, or fatalism must not be allowed, and that the early pre-cancerous danger signals must be watched for. The danger signals enumerated by Dr. Anderson cover so large a field that the average man may be disposed to disregard them. Though it may be difficult to induce the man in the street to read and comprehend the pamphlet, it may be hoped that an impression will be made by the optimism of the final statement—that by early treatment one-third of all male cancers, and one-half of all female cancers can be cured, and that "the present high cancer mortality ought to be, and could be, reduced by nearly 50 per cent."

#### ARTIFICIAL SUNLIGHT TREATMENT OF FREDDIE CHILDREN

The medical officer of the 11th of Huddersfield (Dr. S. G. Moore) has made a report on the open air residential treatment of under-average children at the Cinderella Holiday Home, Honley. It gives an account of an interesting experiment in the treatment of these children with artificial sunlight. There were sixty-two children resident during the past winter the children were separated into two groups, matched in pairs as far as possible, and to one group was given ultra-violet treatment, to the other group none. Both received equal benefits in good housing, good clothing, and good food. The children on admission were undernourished and anæmic. All improved substantially. The results of the experiment are apparently disconcerting. Increase in haemoglobin and in red cells "is in favour of those who received the treatment compared with those who did not, 6.7 per cent contrasting with 8.182 per cent of the former, and 58,600 contrasting with nearly 400,000 of the latter." On the other hand the boys who did not have the light treatment gained on an average 4 lb 2.8 oz in weight as against 3 lb 8.364 oz of those receiving the treatment. The latter gained more in height and less in chest measurement. With the girls there were similar results. It is noted that on admission many of the children were suffering from enlarged veins of the trunk which is regarded as evidence of subnormal respiratory function, and that this defect was greatly improved on discharge.

## Correspondence.

#### THE EPIDEMIOLOGY OF POLIOMYELITIS

SIR,—In a paper upon the epidemiology of poliomyelitis (August 27th, 1927, p. 347), Dr. Walshe calls particular attention to certain suggestions which I have made in connexion with the mode of spread by carriers and brands. I am the author of a series of preposterous statements, in the heat of his argument, which compel my immediate repudiation, further he accuses me—I am sure quite unwittingly—of falsifying Dr. Reece's figures in an allusion to the Stoke Rivers incident in the Devon and Cornwall outbreak of 1911, for the purposes of furthering my argument. I have suggested that a "cancer" epidemic preceding and working up in violence to an epidemic of disease might possibly explain the multitudinous recorded instances in which poliomyelitis has suddenly appeared simultaneously in a number of widely separated localities. Let me quote Dr. Reece's words in connexion with the outbreak above mentioned:

"Poliomyelitis was dispersed all over both counties (Devon and Cornwall) in a short space of time, and apparently the appearance of the disease in many widely separated parts was almost simultaneous, so that it could not have been explained by abortive cases unless these had been present in very large numbers."

I have never used the word "simultaneous" in connexion with the subject of poliomyelitis except in relation to appearance of the disease in widely separated localities. Yet Dr. Walshe accuses me of the statement that

"the presence of this army of carriers leads to the practically simultaneous mass infection of all available susceptible subjects. This manner of spread involves the universal and simultaneous striking down of all susceptible members of the community."

I have never made any such statement, nor can any such interpretation of anything which I have ever said or written be justly arrived at. The absurdity is over-whelming in the light of every recorded epidemic.

Dr. Walshe becomes incomprehensible when he makes me responsible for the "categorical statement that at the moment of infection the virus ceases to be infective, thus rendering case-to-case spread impossible." I have argued that the carrier is the chief means by which the disease is spread. Is not the carrier infected? Is not every case of poliomyelitis of necessity a carrier during the incubation period, since this is a nasopharyngeal infection and readily communicable by droplet infection? What I have said to explain the absence of any proved infectivity from poliomyelitis in the pyrexial stage and thereafter is that the infectivity of the virus wanes very rapidly when the body is

reaction to the disease appears, and in so doing I am in accord with a general principle by which infectious disease is recovered from. For example measles is produced intensely infectious at the moment of appearance of the first symptom and probably for some time before that. Thereafter the infectivity rapidly declines. Dr Walshe will not be able to diminish my denial of proved case-to-case infection so summarily or easily as by referring to the infection of monkeys from a case of poliomyelitis of ten days' duration as readily as from a carrier since the injection of the virus into the central nervous system which is the means by which monkeys are usually (and with great difficulty) infected is not the means by which poliomyelitis is transmitted in the human subject and is no proof of the possibility of nasopharyngeal infection with a virus of the same strength.

The classic Trastena event reported by Wickman—referred to by Dr Walshe—does not in reality support his argument. It proves that six of the fifteen houses infected from the school were infected by a carrier who did not subsequently develop the disease and does not in any way disprove that the other nine houses were infected by carriers who did thereafter develop the disease even though Dr Walshe should deny the evidence of Klump and Pettersen who record that they proved at least two carriers for every developed case of the disease in the infected households that they examined.

The advent of the disease upon one member after another in the same household with a definite period between the onset of each case does not disprove that the infection occurred from the one to the other in the carrier or incubation stage and it does not prove the infectivity of the developed disease.

Dr Walshe comments upon my short reference to the Stoke Rivers outbreak, a swift scourge which, lightning upon the little village of Stoke Rivers laid low in a few days 45 persons out of a total population of 119, as so out of harmony with the facts as to lend no support to his theory, and he proceeds to state that there were but 35 cases, and that the epidemic lasted forty days. I referred to this outbreak as of historic interest and merely used it in support of my theory. My services as to the numbers is supported by the wording of Dr Reece's report.

In the community of 119 persons there were thirty-six attacks by poliomyelitis which were more or less definite. In addition to the thirty-six there were nine others who may possibly have suffered in a minor degree.

Dr Walshe seems to object very much to my description of the curve of incidence in time of cases of poliomyelitis during an epidemic as having characteristically a rapid breeze high peak and rapid fall. Surely this type of curve has been recorded much more often than any other and may be termed justly the most characteristic. The slowly rising and slowly falling flat-topped curves of the low incident epidemics of large towns which I have referred to the "salting" of the community, are, of course well known.

Any mention which I have made of immunity following epidemic poliomyelitis has no reference to my personal experience for in England we have not had successive epidemics incident upon the same community. But it is gathered from the record of the American epidemic, that an epidemic seemed to remove all the susceptibles and in a second epidemic incident upon the same community only those born subsequently to the first epidemic were affected.

When Dr Walshe states that during the last twenty years children admitted to hospital suffering from poliomyelitis in the pre-exal stage have been treated with the precautions usual in infective disease and that their opportunities of spreading infection are restricted in consequence and uses this argument against my contention that cases of acute pre-exal poliomyelitis have repeatedly been admitted to the children's wards of our hospitals, and that no case of spread of infection has ever been recorded, he is surely on very unsafe ground, for at no hospital at which I have served nor at any London hospital at which I have been able to inquire since the appearance of his paper, nor at the hospital where Dr Walshe and I are colleagues,

have any such precautions been taken, and for the reason that experience has never called for them.

The case for the carrier epidemic and the carrier infection has not fallen to the ground and remains entirely sound in spite of this recent comment. Moreover it is in keeping with the trend of recent epidemiological research. The argument for case-to-case infection from the developed disease needs only the one indisputable case to prove it, and that case is not yet forthcoming.

I cannot think that any speculation upon disease nor suggestions which may explain its strange manners made in the light of clinical experience and with a knowledge of the literature will have any of the dire effects Dr Walshe warns his readers against—I am, etc.,

LEONARD W. T. AUSTIN, M.D.

JAMES COLLIER

## ALCOHOL AND THE MOTORIST

SIR—Allow me to pay my tribute of admiration to the valuable scientific work of Dr Clifford Carter, Dr Southgate, Professor McManby, Widmark, Miles and others in their efforts to elucidate the problems involved in alcohol and the driver.

The method of approach along specialized lines is extremely interesting to the police surgeon but for practical purposes we must surely take a broad view of the clinical signs that justify the diagnosis of drunkenness with the corresponding unsuitability to drive. The borderline cases are naturally those of greatest difficulty. In the preliminary stage of intoxication—call it exuberance or hilarity—the man is liable to consider his judgment lost and in fact to take unnecessary risks. Frequently associated with this "superior" judgement there is a reckless, will power coupled with an unsteady mechanism for converting that power into effect.

The definition of a good driver may well be put thus: One who gets a grip of approaching danger in an instant and who has the skill and the power to avoid it. A rapid reaction time is perhaps one of his most valuable possessions. Undoubtedly alcohol delays this reaction time but the degree of interference is not constant and varies in him.

If we admit the pathological condition to be one of damaged association fibres physiological and psychological, with delayed reflex, we are even then confronted by the fact that these paralytic, partial and temporary though they be do not travel *pari passu* in any one individual. It is well to have a list of tests available and to be continually on the lookout for fresh signs and for fresh tests, but in my experience the man himself discloses in his own story the way in which the alcohol has affected him and so affords clear indications for the surgeon's examination.

Not by the quantity of alcohol excreted by any one organ but by his behaviour and the manner of his driving, should a man in my opinion be judged—always providing the surgeon sees him soon after the accident and pronounces him drunk.

Justice would be assisted if the surgeon were permitted to re-examine the man the following morning—I am, etc.,

J. MATHIAS, M.B. Lond.,

Aust. J. H.

Surgeon, Division Metropolitan Police

SIR—I have read with interest the leading article in your issue of August 27th (p. 354) in which you gave appreciative consideration to my paper at the Edinburgh Meeting on the alcoholic urinary concentration as a guide to intoxication. But though appreciative in the main it is critical in detail. May I, therefore, be permitted to draw attention to one or two matters in debate?

I need not emphasize the paramount importance of the general clinical examination of the person concerned, to which every clue must be given. Upon its completion a written statement is required from the doctor giving his diagnosis. This statement is produced in all subsequent legal proceedings. The analytical tests can only follow, later, and confirm or fail to confirm, what has been written and the tests have likewise to be stated in court. It follows that the alcoholic urinary analysis is of greatest value in "borderline cases," and it is in these instances that I most frequently make use of it.

You comment upon the possible illegality of the proceeding. I do not think there is any illegality, and Lord Russell, who presided over our discussion in Edinburgh, is of my opinion. I contend that we have as much right to examine the urine as the breath, or pulse, or reflexes. Indeed, I examine for sugar and albumin at the same time, and might be adversely criticised in court if I did not, as a recent case of which I lately read testifies. The other point is the well known difference in the behaviour of comparative abstainers and toppers who have recently consumed alcohol. Mellinby and Southgate have shown that in the case of the latter there is delayed absorption. They do not readily become drunk and they fail to exhibit a high alcoholic blood content. As they do not become drunk they are not apprehended for being drunk, and consequently do not concern us in this issue. But if, by chance (as recently happened in two of my cases), after a "night out" they do show signs of intoxication, then a high alcoholic urinary concentration will be found. In other words drunkenness will appear in the abstainer and the topper in accordance with how much alcohol is present in the blood (and consequently the urine) at the material time. We are not concerned in any way with how much alcohol a person has consumed. All that signifies is "Is he drunk?" If his blood alcoholic content be high he will inevitably show signs of intoxication, topper or abstainer, whether little or much drink has been needed to produce that effect—I am, etc.,

GODFREY CARTER

## GOITRE REMEDIES

SIR,—Your New Zealand correspondent (August 27th, p 361) seems to take the new health regulations in that country rather seriously. It seems "that iodized salt can safely be used for household purposes, and its use is authorized in breadmaking." As iodized salt only contains 1 grm of potassium iodide, or more likely 1 grain of sodium iodide, in 35 lb of salt the dose of iodide is fairly homeopathic. Moreover, it does not seem to be evenly distributed, as I have never been able to find a trace of iodine under ordinary methods of analysis, in fact, it seems to be as elusive as vitamin. The sodium chloride is all right, and it is an excellent table salt, but I would not pay a fancy price for it in the idea that I was being dosed with iodine. It would be perfectly safe in the hands of those misguided physicians who prescribe iodine and thyroid in exophthalmic goitre. For ordinary goitre allopathic doses are requisite.

In a paper in the *Practitioner*, April, 1914, on the functions of the thyroid, the suprarenal and the pituitary glands, I recorded two cases of exophthalmic goitre caused by large doses of tincture of iodine, and rapidly cured by the substitution of a calcium salt for the iodine.

Youths up to the age of puberty frequently suffer from defective action of the thyroid, and in such cases I have long recommended a large piece of solid iodine, say 2 inches, to be placed in an open cup in the dormitory. This slowly volatilizes into the atmosphere which the patient breathes at night, but usually additional small doses of iodine or an iodide are requisite.

There are very few diseases more easily prevented and cured than the different varieties of goitre. I have never seen a death from exophthalmic goitre since I ceased recommending surgery about a quarter of a century ago—I am, etc.,

## SALARIES OF TEACHING APPOINTMENTS

SIR,—In recent numbers of the JOURNAL the post of surgical tutor which the University of Leeds desires to fill has been refused advertisement and is put on the "black list" on the ground, I believe, that the salary offered is £500 instead of the £600 which the Association's scale requires. May I suggest that the Association is not acting in the best interests of the progress of medicine when it tries to extend the policy which has succeeded so admirably in professional appointments to the sphere of university education, with which it is not concerned?

The advantages which are open to a young graduate holding a junior teaching appointment in a university are

enormous, he has the opportunity of devoting himself wholeheartedly for two or three years to learning his subject in a real way and gaining a unique equipment for whatever line he selects to take up for life. For such post-graduate education I think sometimes payment might be asked instead of given. It is, however, necessary for even the most earnest students to live, and universities offer a great number of small appointments which enable young men and women to do that in decency if not in comfort. It is quite impossible for them to pay at the rate which the Association (I dare say quite rightly) demands for professional as distinct from educational services, nor would it, I think, be right for them to do so. Those who hold these appointments get at least as much as they give, and the only consequence of the action which the Association is attempting will be to diminish the number of young medical graduates who can take advantage of the splendid educational opportunities which are offered to them—I am, etc.,

A E BOYCOTT

## MEDICAL CONFIDENCES

SIR,—Dr Gemmell (August 20th, p 329) seems to hold the view that priests who hear confessions could give valuable evidence in legal trials, and that they are exempted from being called upon to break faith with their penitents because they are more determined in their resistance than are doctors.

The difference in treatment is better explained possibly by the difference in value of priests and doctors respectively as witnesses. A doctor is a much more valuable witness than a priest would be. His evidence consists chiefly of his observations and opinions, whereas a priest can say only what has been told to him.

Further, there can seldom be any difficulty in finding out which doctor has been attending a patient who is a party to a lawsuit, whereas it would usually be impossible to discover to which priest any particular confession has been made, nor could it be known whether the person whose confession was required for evidence had confessed the action or conduct with which the trial was concerned.

If the required doctor were as little discoverable as the required priest, and if his evidence were confined to relating the verbal confidences that he had received from his patient, he would be as little troubled by subpoenas as is the priest.—I am, etc.,

Wales Colne, Essex, Aug 21st
